# 1 About the Document

## 1.1 Purpose

The purpose of this document is to provide detailed information on writing components, for example, test ports, and so on, for executable test suites.

## 1.2 Target Groups

This document is intended for programmers of TTCN-3 test suites with information in addition to that provided in the TITAN User Guide [\[13\]](#). It is recommended that the programmer reads the TITAN User Guide before reading this document.

## 1.3 Typographical Conventions

This document uses the following typographical conventions:

- **Bold** is used to represent graphical user interface (GUI) components such as buttons, menus, menu items, dialog box options, fields and keywords, as well as menu commands. Bold is also used with '+' to represent key combinations. For example, **Ctrl+Click**
- The character '/' is used to denote a menu and sub-menu sequence. For example, **File / Open**.
- Monospaced font is used represent system elements such as command and parameter names, program names, path names, URLs, directory names and code examples.
- Bold monospaced font is used for commands that must be entered at the Command Line Interface (CLI).

Prepared (Subject resp) ETHBAAT Jeno Balasko		No. 2/198 17-CRL 113 200/5 Uen

## 2 TTCN-3 Limitations in this Version

The present Test Executor is an implementation of TTCN-3 Core Language standard ([1]) with support of ASN.1 ([3]). However, the following TTCN-3 language constructs are not supported in the current version of the Test Executor. When applicable, the relevant clause of the standard text ([1]) is given within parentheses after each limitation. The list of ASN.1 related limitations can be found in chapter 4.25.

- C++ code generation for parameterized local templates is not supported.<sup>1</sup> (5.0, relevant cells of Table 1)
- Parameterized TTCN-3 `record`, `set` and `union` types. (5.4 in [1])
- TTCN-3 sub-typing constraints are checked only at compilation time. In the run-time environment the restricted types are substituted with the corresponding base type and no run-time error is produced if the assigned value violates the subtype constraint.
- The special TTCN-3 type `anytype` is supported with restrictions. (6.2.6 in [1])
- Type compatibility of structured types.<sup>2</sup> (6.3 in [1])
- Two (non-empty) component types are considered to be compatible only if the compatibility relation is explicitly specified by the test suite writer. Details can be found in section 4.21. (6.3.3 and 9.3 in [1])
- Selective import statements. All TTCN-3 imports are treated as `import all`.<sup>3</sup> (8.2.3 and F.2 in [1])
- Type `address` must not be an external type specified outside TTCN-3. The special value `null` cannot be assigned to variables of type `address`. (9.6 in [1])
- The compiler does not check whether a TTCN-3 function invoked from within a `template`, Boolean guard expression of an `alt` construct, local variable initializer of an `altstep` or an `interleave` statement has side-effects. The run-time behavior is undefined if a function with side-effects (e.g. communication operations) is called while one of the above statements is being executed. (20 in [1])

<sup>1</sup> The semantic analyzer is able to verify modules with such definitions, but the generated C++ code will be incomplete or erroneous.

<sup>2</sup> Type compatibility for structured types is enabled only in the function test run-time due to performance considerations. In the load test run-time aliased types and sub-types are treated to be equivalent to their unrestricted root types. Different structured types are incompatible to each other. Two array types are compatible if both have the same size and index offset and the element types are compatible according to the rules above.

<sup>3</sup> Recursive and non-recursive import means exactly the same when importing all definitions from a module.

Prepared (Subject resp) ETHBAAT Jeno Balasko		No. 2/198 17-CRL 113 200/5 Uen		
Approved (Document resp) ETHLEL Elemer Lelik	Checked ETHGRY	Date 2015-05-15	Rev C	Reference

- The `disconnect` and `unmap` operations cannot refer to multiple connections or mappings. (21.1.2, relevant parts in [\[1\]](#))
- The `send` and `call` operations cannot be used for multicast or broadcast communication. (22.2.1 and 22.3.1 in [\[1\]](#))
- Attributes of type definitions cannot be changed when they are being imported. (27.1.2.1 in [\[1\]](#))
- Template instances cannot be used in the `to` clause of communication operations. Only values of `component` and `address` types are allowed. (stated only in BNF)
- The additional predefined function `decomp` is not implemented. (D.2 of [\[3\]](#))
- In `port` type definitions the list of incoming and outgoing message types or signatures must be explicitly specified, the `all` keyword is ignored by the compiler. (G.3 in [\[1\]](#))
- The TTCN-3 and ASN.1 modules are identified only by their names. Object identifiers in module headers are ignored. Module object identifiers in `import` statements and references are skipped without any checking, the semantic analyzer uses the module identifier only. (7.2.3 of [\[3\]](#), 8.1 in [\[1\]](#))
- The comparison operators do not work on `objid` values. Only the equality (`==`) and non-equality (`!=`) operators are allowed. (7.2.5.2 of [\[3\]](#), 7.1.3 in [\[1\]](#))
- Templates can not be used in the parameter of `encvalue` built-in function. (C.38 in [\[1\]](#))
- The declaration of object identifiers can only point to constant values, references to variables are not supported.
- The Configuration and Deployment Support and the Advanced Parameterization packages of the TTCN-3 standard are not supported yet (FIXME references).
- In contrast to the standard, TITAN does not allow applying the same name to a structured type and to an element of the same type.
- From version 1.8.pl3 (or R8D) the logging machinery uses an internal TTCN-3 module, named `TitanLoggerApi`, hence using this module name in user code is not allowed.
- Referencing into an omitted field of any non-const variable/template of record/set type is allowed and it will expand the structure to the level of reference. All the expanded fields under `omit` will be unbound. This

Prepared (Subject resp) ETHBAAT Jeno Balasko		No. 2/198 17-CRL 113 200/5 Uen		
Approved (Document resp) ETHLEL Elemer Lelik	Checked ETHGRY	Date 2015-05-15	Rev C	Reference

behavior is TITAN specific. According to the TTCN-3 standard (15.6.2 of [\[1\]](#)), the proper behavior would be a dynamic test case error in this situation.

In case of variable templates referencing into a matching mechanism will change the template regardless of it being a left hand side or a right hand side value.

In case of non-variable templates referencing into a matching mechanism will cause an error. According to the TTCN-3 standard the proper behavior for right hand side templates would be to return an expanded value but not change it's own value in case of AnyValue matching mechanism or stop with an error in case of other matching mechanisms.

- According to the standard, before matching the tools have to make sure that the template being used is completely initialized, with no fields or elements left unbound. For performance reasons this check is not done before the matching is done. Instead the matching will report the error, when it tries to use an unbound field or elements.
- In case the compiler is not able to decide at compile time, if all possible execution branches contain a return statement, that is, in cases of alt statements, loops and branching statement like if-else, select case, and so on, it will report an error without generating code.

For example:

```
function f_check() return boolean {  
    for (var integer i:=0; i < some_variable; i := i + 1) {  
        return true;  
    }  
}
```

In this case the compiler will report an error as it can not evaluate, if the loop will be executed at least once, and if the loop is not executed, the end of the function would be reached without a return statement.

The workaround for this kind of problem is easy, the user needs to insert an extra return statement at the end of the function, like:

```
function f_check() return boolean {  
    for (var integer i:=0; i < some_variable; i := i + 1) {  
        return true;  
    }  
    return false  
}
```

- The language specification, after the “language” keyword, is ignored by the compiler.
- For record of/set of types of fixed size, which have a length restriction of one concrete value, and arrays the `sizeof()` and `lengthof()` predefined functions are not standard compliant: `sizeof()` returns the number of elements, `lengthof()` returns the index of the last initialized element plus one.

Prepared (Subject resp) ETHBAAT Jeno Balasko		No. 2/198 17-CRL 113 200/5 Uen		
Approved (Document resp) ETHLEL Elemer Lelik	Checked ETHGRY	Date 2015-05-15	Rev C	Reference

- IPv6 networking between the MC, HC and Parallel Test Components is supported only on Linux and Cygwin 1.7.
- The optional "implicit omit" attribute is not applied recursively.

Prepared (Subject resp) ETHBAAT Jeno Balasko		No. 2/198 17-CRL 113 200/5 Uen		
Approved (Document resp) ETHLEL Elemer Lelik	Checked ETHGRY	Date 2015-05-15	Rev C	Reference

### 3 Clarifications to the TTCN-3 Standard

The TTCN-3 Core Language standard ([\[1\]](#)) and its Operational Semantics ([\[1\]](#)) give ambiguous description for some language constructs. This section specifies our resolution for these ambiguities that was followed during the implementation of our compiler and run-time environment.

#### 3.1 Predefined Function Identifiers

The standard does not clarify the status of predefined function identifiers, that is, the names of functions defined in Annex C of [\[1\]](#). In our interpretation these words cannot be used to identify user-defined TTCN-3 entities because such a definition would hide the predefined function completely. Thus our compiler treats these identifiers in the same way as the normal keywords of the language. Therefore the inappropriate use of predefined functions, for example wrong number of arguments, will result in syntax errors rather than semantic errors.

#### 3.2 Meaning of `any` and `all`

The meaning of the keywords is only loosely defined in the standard. The resulting equivocality concerns timer, port and component operations.

##### 3.2.1 Timer and Port Operations

The meaning of keywords `any` and `all` in timer and port operations is unclear. These constructs might be resolved statically at compilation time by applying the operation on all visible timers and ports of the given scope unit. Our run-time environment, however, implements a dynamic resolution, that is, it walks through the list of active timers and ports and applies the respective operation. As a consequence of this, such operations are also applicable in scope units without visible timers and ports, for example in functions without `runs on` clause. Because of the run-time evaluation there is one limitation, which is verified by our semantic analyzer: the receiving port operations, that is, `receive`, `trigger`, `getcall`, `getreply`, `catch` and `check`) that refer to `any port` cannot have template parameter and `value` or `param redirect`. To avoid incompatibilities with future versions it is not recommended to use `any` or `all` in timer and port operations.

##### 3.2.2 Component Operations

The standard does not specify explicitly the behavior of the component operations that refer to `all component` when only the MTC exists, that is, no PTC had been created during the testcase. In our implementation both `all component.running` and `all component.alive` return `true` and the operations `all component.done` and `all component.killed` succeed immediately in this situation. Operations `all component.stop` and

Prepared (Subject resp) ETHBAAT Jeno Balasko		No. 2/198 17-CRL 113 200/5 Uen		
Approved (Document resp) ETHLEL Elemer Lelik	Checked ETHGRY	Date 2015-05-15	Rev C	Reference

`all component.kill` do nothing; instead, a warning is issued. The same rules are applied in single mode, when it is impossible to create PTCs, as well.

### 3.3 Response and Exception Handling Parts

The behavior of the response and exception handling part of a `call` operation is not clearly specified in the standard. The allowed `getreply` and `catch` operations can handle only the possible responses and exceptions of the previous signature call. In our implementation if any other event arrives into the port queue during the execution of the response and exception handling part it may block the execution forever. The runtime environment generates a dynamic test case error in such a situation. If the test suite writer expects any other event on the same port during the outstanding call, for example a simultaneous incoming call initiated by the other side, a non-blocking call operation with the keyword `nowait` should be used. The response and the possible incoming calls should be handled in a forthcoming regular `alt` construct using the appropriate `getreply` and `getcall` operations.

### 3.4 Variable Lists in `param Redirect`

In the standard, it is not clear that the `VariableList` notation in the `param redirect` of `getcall` and `getreply` operations should refer to **all** parameters of the respective signature or to the **relevant** parameters<sup>4</sup> only. Our compiler expects variable entries only for the relevant parameters and ignores the irrelevant ones. This is because otherwise the test writer should use `NotUsedSymbols` for all irrelevant parameters, which would be a redundant notation. For example, if a signature has one `in`, one `out` and one `inout` parameter the compiler expects two variable entries in both `getcall` and `getreply` operations.

### 3.5 References between Language Elements

The TTCN-3 standard does not specify clearly the permitted references between different kinds of language elements. The following table shows our interpretation.

---

<sup>4</sup> Relevant parameters are the `in` and `inout` parameters in case of `getcall` operation as well as `out` and `inout` ones in case of `getreply`.

Prepared (Subject resp) ETHBAAT Jeno Balasko		No. 2/198 17-CRL 113 200/5 Uen		
Approved (Document resp) ETHLEL Elemer Lelik	Checked ETHGRY	Date 2015-05-15	Rev C	Reference

*Table 1 References between TTCN-3 elements*

Referred element Referring element	Literal value	Constant	External constant	Module parameter	Template
Constant	Y	Y*	N	N	N
Array size	Y	Y	N	N	N
Subtype constraint	Y	Y	N	N	N
Default value of module parameter	Y	Y	Y	N	N
Actual value of module parameter (in configuration file)	Y	N	N	N	N
Default duration of timer	Y	Y	Y	Y	N
Template (non-parameterized)	Y	Y	Y	Y	Y*

**Legend:**

- N Not allowed by the TTCN–3 language.
- Y Allowed and fully supported by the current version of this TTCN–3 tool.
- Y\* Allowed and fully supported, but circular reference chains must be avoided.

**Notes:**

- The above table implies that the value of all constants and the attributes of all type constructs (type constraints, array sizes, etc.) shall be known at compilation time.
- ASN.1 value assignments are treated as TTCN–3 constants.

Prepared (Subject resp) ETHBAAT Jeno Balasko		No. 2/198 17-CRL 113 200/5 Uen		
Approved (Document resp) ETHLEL Elemer Lelik	Checked ETHGRY	Date 2015-05-15	Rev C	Reference

- The value of constants shall refer only to built-in operators or additional predefined functions.
- The body of non-parameterized templates and the default duration of timers shall be known at test startup (load) time when all module parameters are known.
- The actual parameters of templates or the actual duration of timers shall be determined run-time because the actual value of variables may be referred.
- The rules for a language element do not depend on its scope unit. For example the same rules apply on module, component and local (function, testcase, altstep) constants.

### 3.6 Encoding Rules

The standard does not specify clearly some of the encoding rules.

- The encoding of fields in `record`, `set` and `union` types is supported.
- The order of attributes of the same type in a `with` statement is important. The second variant might override the first, or an overriding attribute will override all the following attributes of the same type.
- Encode attributes are an exception to this as they are not really attributes, but "contexts". It cannot be determined to which encode "context" the variants of the same `with` statement should belong if there are several. As having several encode "contexts" in the same `with` statement would be a bad coding practice, a warning is generated and the last encode is used as the statement's encode "context".
- As encodes are contexts, an encode is only overridden if the overriding context is not the same.
- The order of attributes of different type in a `with` statement is not important, they do not affect each other.
- In case of structured types, the encode context of the type is the encode context of its fields too, if the fields do not override this attribute. The other attribute types are handled separately for the structured type and its fields. Attributes inherited from higher level (module/group/structured type) might change the encoding of a record and that of its fields.
- Attributes with qualifiers referring to the same field are handled as if they were separate `with` statements. The same rules apply to them. For example, the last encode from the ones referring to the same field is taken as the encoding context of the field.

Prepared (Subject resp) ETHBAAT Jeno Balasko		No. 2/198 17-CRL 113 200/5 Uen		
Approved (Document resp) ETHLEL Elemer Lelik	Checked ETHGRY	Date 2015-05-15	Rev C	Reference

- Attributes belonging to a field of a structured type or a type alias have the following overwriting rules. A new `variant` attribute together with the directive `override` clears all current attributes defined for the type of the field. A new `variant` attribute without the directive `override` overwrites only the current `variant` attribute, all other attributes remain unchanged.

### 3.7 Address Type

The standard does not specify clearly the status of special TTCN-3 type `address`. Our implementation is based on the rules below.

The test suite writer can assign the name `address` to a regular data type. There can be at most one type named `address` in each TTCN-3 module. It is allowed that different modules of the test suite assign the name `address` to different types.

The name `address` cannot be assigned to the following TTCN-3 types:

- port types
- component types<sup>5</sup>
- signatures
- the built-in type `default`<sup>6</sup>

Whenever the word `address` is used as a type, it is assumed to be a reference to the type named `address` in the current module. The type named `address` cannot be imported into another TTCN-3 module, that is, it can be referenced using the name `address` only within its own module. If one wants to use this type in other modules a regular alternate name must be assigned to it with type aliasing.

Addressing the SUT in communication operations is allowed only if the `address` type is defined in the same module as the corresponding port type. In addition, the port type must have a special `extension` attribute to support `address` values (See section “Support of address type” in [\[16\]](#) for more details).

Note that it is possible to use different address types on different ports in the same TTCN-3 module if the respective port types are imported from different

<sup>5</sup> If component types were allowed for addressing the compiler would not be able to decide whether a component reference in the `to` or `from` clause of a communication operation denotes a test component, which is reachable through a port connection or an address inside the SUT, which is reachable through a port mapping.

<sup>6</sup> The values of type `default` (i.e. the TTCN-3 default references) cannot be passed outside the test component by any means.

Prepared (Subject resp) ETHBAAT Jenő Balasko		No. 2/198 17-CRL 113 200/5 Uen		
Approved (Document resp) ETHLEL Elemer Lelik	Checked ETHGRY	Date 2015-05-15	Rev C	Reference

modules, but neither address type may be referenced with name `address` by the importing module.

### 3.8 Importing `import` Statement from TTCN-3 Modules

See [18] standard for detailed description. Additional information for better understanding:

- Import (see following chapters of the [18] standard 8.2.3.1-8.2.3.6, and 8.2.5, only applies for global definitions (see [18] table 8. in 8.2.3.1), therefore import functionality is not interfered by import of import statement.
- Import statement can be imported by only import of import statement (chapter 8.2.5 and 8.2.3.7).
- Import statements are by default private, importing of import statement with public or friend visibility is recursively resolved, and thus importing of importing of import statement is possible.
- Importing of import statement - in case of friend visibility -recursive resolving is broken, if the import chain has a member that is not friend of the exporting module.
- Importing of import statement circular import chain causes error.
- Example for friend type and importing of import statement

```
B.ttcn      // friend template
friend module C, E;

friend template integer t_B_i_fr := 0;

C.ttcn      // public import and importing of import statement, friend of B
public import from B all;
public import from B {import all};

D.ttcn      // public import and importing of import statement, NOT friend of B
public import from C all;
public import from C { import all };

E.ttcn      // public import and importing of import statement, friend of B
public import from D { import all };
public import from D all;

testcase tc_B() runs on MTC {
    var integer i:=valueof(t_B_i_fr); //Visible!
    setverdict(pass);
}
```

### 3.9 Description of Behavior Types Syntax

TITAN supports the behaviour type package of the TTCN-3 standard, but with a different syntax. For details of the behaviour types see [20].

Table 2 Behaviour types - refers shows the different syntax of the function behaviour type.

Prepared (Subject resp) ETHBAAT Jeno Balasko		No. 2/198 17-CRL 113 200/5 Uen		
Approved (Document resp) ETHLEL Elemer Lelik	Checked ETHGRY	Date 2015-05-15	Rev C	Reference

**Table 2      Behaviour types - refers**

Standard (6.2.13.2 in [20])	Titan specific syntax
<pre>type function MyFunc3 ( in integer p1 ) return charstring;  var MyFunc3 myVar1 := int2char;</pre>	<pre>var MyFunc3 myVar1 := refers(int2char);</pre>

Note that the functionality is same as in the standard, only the syntax is different.

The syntax of the apply operation is different, see Table 3      Behaviour types - apply and derefers

Standard:

## 4 TTCN–3 Language Extensions

The Test Executor supports the following non-standard additions to TTCN–3 Core Language in order to improve its usability or provide backward compatibility with older versions.

### 4.1 Syntax Extensions

The compiler does not report an error or warning if the semi-colon is missing at the end of a TTCN–3 definition although the definition does not end with a closing bracket.

The statement block is optional after the guard operations of `altsteps`, `alt` and `interleave` constructs and in the response and exception handling part of `call` statements. A missing statement block has the same meaning as an empty statement block. If the statement block is omitted, a terminating semi-colon must be present after the guard statement.

The standard escape sequences of C/C++ programming languages are recognized and accepted in TTCN–3 character string values, that is, in literal values of `charstring` and `universal charstring` types, as well as in the arguments of built-in operations `log()` and `action()`. Note that as a consequence of the extended escape sequences and in contrast with the TTCN–3 standard, the backslash character itself has to be always duplicated within character string values.

The following table summarizes all supported escape sequences of TTCN–3 character string values:

Table 4 Character string escape sequences

Escape sequence	Character code (decimal)	Meaning
<code>\a</code>	7	bell
<code>\b</code>	8	backspace
<code>\f</code>	12	new page
<code>\n</code>	10	line feed
<code>\r</code>	13	carriage return
<code>\t</code>	9	horizontal tabulator
<code>\v</code>	11	vertical tabulator
<code>\\</code>	92	backslash
<code>\"</code>	34	quotation mark

Prepared (Subject resp) ETHBAAT Jeno Balasko		No. 2/198 17-CRL 113 200/5 Uen		
Approved (Document resp) ETHLEL Elemer Lelik	Checked ETHGRY	Date 2015-05-15	Rev C	Reference

Escape sequence	Character code (decimal)	Meaning
\'	39	apostrophe
\?	63	question mark
\ <newline>	nothing	line continuation
\NNN	NNN	octal notation (NNN is the character code in at most 3 octal digits)
\xNN	NN	hexadecimal notation (NN is the character code in at most 2 hexadecimal digits)
""	34	quotation mark (standard notation of TTCN-3 )

Note that only the standardized escape sequences are recognized in matching patterns of character string templates because they have special meaning there. For example, inside string patterns `\n` denotes a set of characters rather than a single character.

Although the standard requires that characters of TTCN-3 `charstring` values must be between 0 and 127, TITAN allows characters between 0 and 255. The printable representation of characters with code 128 to 255 is undefined.

The compiler implements an ASN.1-like scoping for TTCN-3 enumerated types, which means it allows the re-use of the enumerated values as identifiers of other definitions. The enumerated values are recognized only in contexts where enumerated values are expected; otherwise the identifiers are treated as simple references. However, using identifiers this way may cause misleading error messages and complicated debugging.

The compiler allows the local definitions (constants, variables, timers) to be placed in the middle of statement blocks, that is, after other behavior statements. The scope of such definitions extends from the statement following the definition to the end of the statement block. Forward-referencing of local definitions and jumping forward across them using `goto` statements are not allowed.

The compiler accepts in-line compound values in the operands of TTCN-3 expressions although the BNF of the standard allows only single values. The only meaningful use of the compound operands is with the comparison operators, that is, `==` and `!=`. Two in-line compound values cannot be compared with each other because their types are unknown; at least one operand of the comparison must be a referenced value. This feature has a limitation: In the places where in-line compound templates are otherwise

Prepared (Subject resp) ETHBAAT Jenö Balasko		No. 2/198 17-CRL 113 200/5 Uen		
Approved (Document resp) ETHLEL Elemer Lelik	Checked ETHGRY	Date 2015-05-15	Rev C	Reference

accepted by the syntax (e.g. in the right-hand side of a variable assignment or in the actual parameter of a function call) the referenced value shall be used as the left operand of the comparison. Otherwise the parser gets confused when seeing the comparison operator after the compound value.

Examples:

```
// invalid since neither of the operands is of known type
if ({ 1, 2 } == { 2, 1 }) { }
```

```
// both are valid
while (v_myRecord == { 1, omit }) { }
if ({ f1 :=1, f2 := omit } != v_mySet) { }
```

```
// rejected because cannot be parsed
v_myBooleanFlag := { 1, 2, 3 } == v_myRecordOf;
f_myFunctionTakingBoolean({ 1, 2, 3 } != v_mySetOf);
```

```
// in reverse order these are allowed
v_myBooleanFlag := v_myRecordOf == { 1, 2, 3 };
f_myFunctionTakingBoolean(v_mySetOf != { 1, 2, 3 });
```

## 4.2 Visibility Modifiers

TITAN defines 3 visibility modifiers for module level definitions, and component member definitions: public, private, friend (8.2.5 in [\[1\]](#)).

On module level definitions they mean the following:

- The public modifier means that the definition is visible in every module importing its module.
- The private modifier means that the definition is only visible within the same module.
- The friend modifier means that the definition is only visible within modules that the actual module declared as a friend module.

If no visibility modifier is provided, the default is the public modifier.

In component member definitions they mean the followings:

- The public modifier means that any function/testcase/altstep running on that component can access the member definition directly.
- The private modifier means that only those functions/testcases/altsteps can access the definition which runs on the component type directly. If they run on a component type extending the one containing the definition, it will not be directly visible.

The friend modifier is not available within component types.

Example:

Prepared (Subject resp) ETHBAAT Jeno Balasko		No. 2/198 17-CRL 113 200/5 Uen		
Approved (Document resp) ETHLEL Elemer Lelik	Checked ETHGRY	Date 2015-05-15	Rev C	Reference

```
module module1
{
import from module2 all;
import from module3 all;
import from module4 all;

const module2Type akarmi1 := 1; //OK, type is implicitly public
const module2TypePublic akarmi2 := 2; //OK, type is explicitly public
const module2TypeFriend akarmi3 := 3; //OK, module1 is friend of module2
const module2TypePrivate akarmi4 := 4; //NOK, module2TypePrivate is private to
module2

const module3Type akarmi5 := 5; //OK, type is implicitly public
const module3TypePublic akarmi6 := 6; //OK, type is explicitly public
const module3TypeFriend akarmi7 := 7; //NOK, module1 is NOT a friend of module3
const module3TypePrivate akarmi8 := 8; //NOK, module2TypePrivate is private to
module2

type component User_CT extends Lib4_CT {};
function f_set3_Lib4_1() runs on User_CT { v_Lib4_1 := 0 } //OK
function f_set3_Lib4_2() runs on User_CT { v_Lib4_2 := 0 } //OK
function f_set3_Lib4_3() runs on User_CT { v_Lib4_3 := 0 } //NOK, v_Lib4_3 is
private
}

module module2
{
friend module module1;

type integer module2Type;
public type integer module2TypePublic;
friend type integer module2TypeFriend;
private type integer module2TypePrivate;
} // end of module

module module3
{
type integer module3Type;
public type integer module3TypePublic;

private type integer module3TypePrivate;
} // end of module
module module4 {

type component Lib4_CT {
var integer v_Lib4_1;
public var integer v_Lib4_2;
private var integer v_Lib4_3;
}
```

### 4.3 The anytype

The special TTCN-3 type `anytype` is defined as shorthand for the union of all known data types and the address type (if defined) in a TTCN-3 module. This would result in a large amount of code having to be generated for the `anytype`, even if it is not actually used. For performance reasons, Titan only generates this code if a variable of `anytype` is declared or used, and does not create fields in the `anytype` for all data types. Instead, the user has to specify which types are needed as `anytype` fields with an extension attribute at module scope.

Examples:

Prepared (Subject resp) ETHBAAT Jeno Balasko		No. 2/198 17-CRL 113 200/5 Uen		
Approved (Document resp) ETHLEL Elemer Lelik	Checked ETHGRY	Date 2015-05-15	Rev C	Reference

```
module elsewhere {
  type float money;
  type charstring greeting;
}

module local {
  import from elsewhere all;

  type integer money;

  type record MyRec {
    integer i,
    float f
  }

  control {
    var anytype v_any;
    v_any.integer := 3;
    // ischosen(v_any.integer) == true

    v_any.charstring := "three";
    // ischosen(v_any.charstring) == true

    v_any.greeting := "hello";
    // ischosen(v_any.charstring) == false
    // ischosen(v_any.greeting) == true

    v_any.MyRec := { i := 42, f := 0.5 }
    // ischosen(v_any.MyRec) == true

    v_any.integer := v_any.MyRec.i - 2;
    // back to ischosen(v_any.integer) == true

    v_any.money := 0; // local money i.e. integer
                    // not elsewhere.money (float)
    // ischosen(v_any.integer) == false
    // ischosen(v_any.money) == true

    // error: no such field (not added explicitly)
    // v_any.float := 3.1;

    // error: v_any.elsewhere.money
  }

  with {
    extension "anytype integer, charstring" // adds two fields
    extension "anytype MyRec" // adds a third field
    extension "anytype money" // adds the local money type
    //not allowed: extension "anytype elsewhere.money"
    extension "anytype greeting" // adds the imported type
  }
```

In the above example, the `anytype` behaves as a union with five fields named "integer", "charstring", "MyRec", "money" and "greeting". The `anytype` extension attributes are cumulative; the effect is the same as if a single extension attribute contained all five types.

Note that the field "greeting" of type `charstring` is distinct from the field "charstring" even though they have the same type (same for "integer" and "money").

Types imported from another module (elsewhere) can be added to the `anytype` of the importing module (local) if the type can be accessed with its unqualified name, which requires that it does not clash with any local type. In the example, the imported type "greeting" can be added to the `anytype` of

Prepared (Subject resp) ETHBAAT Jenő Balasko		No. 2/198 17-CRL 113 200/5 Uen		
Approved (Document resp) ETHLEL Elemer Lelik	Checked ETHGRY	Date 2015-05-15	Rev C	Reference

module local, but “money” (a float) clashes with the local type “money” (an integer). To use the imported “money”, it has to be qualified with its module name, for example a variable of type `elsewhere.money` can be declared, but `elsewhere.money` can not be used as an anytype field.

## 4.4 Ports and Test Configurations

If all instances of a TTCN-3 port type are intended to be used for internal communication only (i.e. between two TTCN-3 test components) the generation and linking of an empty Test Port skeleton can be avoided. If the attribute `with { extension "internal" }` is appended to the port type definition, all C++ code that is needed for this port will be included in the output modules.<sup>7</sup>

If the user wants to use `address` values in `to` and `from` clause and sender redirect of TTCN-3 port operations the `with { extension "address" }` attribute shall be used in the corresponding port type definition(s) to generate proper C++ code. Note that when `address` is used in port operations the corresponding port must have an active mapping to a port of the test system interface, otherwise the operation will fail at runtime. Using of `address` values in `to` and `from` clauses implicitly means system as component reference. (See section “Support of address type” in [\[16\]](#) for more details).<sup>8</sup>

Unlike the latest TTCN-3 standard, our run time environment allows to connect a TTCN-3 port to more than one ports of the same remote test component. When these connections persist (usually in transient states), only receiving is allowed from that remote test component, because the destination cannot be specified unambiguously in the `to` clause of the `send` operation. Similarly, it is allowed to `map` a TTCN-3 port to more than one ports of the system, although it is not possible to send messages to the SUT.

## 4.5 Parameters of `create` Operation

The built-in TTCN-3 `create` operation can take a second, optional argument in the parentheses. The first argument, which is the part of the standard, can assign a name to the newly created test component. The optional, non-standard second argument specifies the location of the component. Also the second argument is a value or expression of type `charstring`.

According to the standard the component name is a user-defined attribute for a test component, which can be an arbitrary string value containing any kind of characters including whitespace. It is not necessary to assign a unique name for each test component; several active test components can have the same name at the same time. The component name is not an identifier; it cannot be used to address test components in configuration operations as

<sup>7</sup> The extension attributes “internal” and “address” are mutually exclusive.

<sup>8</sup> The extension attributes “internal” and “address” are mutually exclusive.

Prepared (Subject resp) ETHBAAT Jeno Balasko		No. 2/198 17-CRL 113 200/5 Uen		
Approved (Document resp) ETHLEL Elemer Lelik	Checked ETHGRY	Date 2015-05-15	Rev C	Reference

component references can. The name can be assigned only at component creation and it cannot be changed later.

Component name is useful for the following purposes:

- it appears in the printout when logging the corresponding component reference;
- it can be incorporated in the name of the log file (see the metacharacter `%n` in section [0](#));
- it can be used to identify the test component in the configuration file (when specifying test port parameters (see section [7.2](#)), component location constraints (see section [7.10](#)) and logging options (see sections [7.2.4](#) and [7.2.5](#)).

Specifying the component location is useful when performing distributed test execution. The value used as location must be a host name, a fully qualified domain name, an IP address or the name of a host group defined in the configuration file (see section [7.9](#)). The explicit specification of the location overrides the location constraints given in the configuration file (see section [7.10](#) for detailed description). If no suitable and available host is found the `create` operation fails with a dynamic test case error.

If only the component name is to be specified, the second argument may be omitted. If only the component location is specified a `NotUsedSymbol` shall be given in the place of the component name.

Examples:

```
// create operation without arguments
var MyCompType v_myCompRef := MyCompType.create;

// component name is assigned
v_myCompRef := MyCompType.create("myCompName");

// component name is calculated dynamically
v_myCompArray[i] := MyCompType.create("myName" & int2str(i));

// both name and location are specified (non-standard notation)
v_myCompRef := MyCompType.create("myName", "heintel");

// only the location is specified (non-standard notation)
v_myCompRef := MyCompType.create(-, "159.107.198.97") alive;
```

## 4.6 Altsteps and Defaults

According to the TTCN-3 standard an `altstep` can be activated as `default` only if all of its value parameters are `in` parameters. However, our compiler and run-time environment allows the activation of altsteps with `out` or `inout` value or template parameters as well. In this case the actual parameters of the activated `default` shall be the references of variables or

Prepared (Subject resp) ETHBAAT Jenő Balasko		No. 2/198 17-CRL 113 200/5 Uen		
Approved (Document resp) ETHLEL Elemer Lelik	Checked ETHGRY	Date 2015-05-15	Rev C	Reference

template variables that are defined in the respective component type. This restriction is in accordance with the rules of the standard about timer parameters of activated defaults. Note that passing local variables or timers to defaults is forbidden because the lifespan of local definitions might be shorter than the `default` itself, which might lead to unpredictable behavior if the `default` is called after leaving the statement block that the local variable is defined in. Since ports can be defined only in component types, there is no restriction about the `port` parameters of `altsteps`. These restrictions are not applicable to direct invocations of `altsteps` (e.g. in `alt` constructs).

The compiler allows using a statement block after `altstep` instances within `alt` statements. The statement block is executed if the corresponding `altstep` instance was chosen during the evaluation of the `alt` statement and the `altstep` has finished without reaching a `repeat` or `stop` statement. This language feature makes the conversion of TTCN-2 test suites easier. Note that this construct is valid according to the TTCN-3 BNF syntax, but its semantics are not mentioned anywhere in the standard text.

The compiler accepts `altsteps` containing only an `[else]` branch. This is not allowed by the BNF as every `altstep` must have at least one regular branch (which can be either a guard statement or an `altstep` instance). This construct is practically useful if the corresponding `altstep` is instantiated as the last branch of the alternative.

## 4.7 Interleave Statements

The compiler realizes TTCN-3 `interleave` statements using a different approach than it is described in section 7.5 of [\[1\]](#). The externally visible behavior of *the* generated code is equivalent to that of the canonical mapping, but our algorithm has the following advantages:

- Loop constructs `for`, `while` and `do-while` loops are accepted and supported without any restriction in `interleave` statements. The transformation of statements is done in a lower level than the TTCN-3 language, which does not restrict the embedded loops.
- Statements `activate`, `deactivate` and `stop` can also be used within `interleave`. The execution of these statements is atomic so we did not see the reason why the standard forbids them.
- The size of our generated code is linear in contrast to the exponential code growth of the canonical algorithm. In other words, the C++ equivalent of every embedded statement appears exactly once in the output.
- The run-time realization does not require any extra operating system resources, such as multi-threading.

Prepared (Subject resp) ETHBAAT Jenő Balasko		No. 2/198 17-CRL 113 200/5 Uen		
Approved (Document resp) ETHLEL Elemer Lelik	Checked ETHGRY	Date 2015-05-15	Rev C	Reference

## 4.8 Logging Disambiguation

The TTCN-3 `log` statement provides the means to write logging information to a file or display on console (standard error). Options `FileMask` (7.2.4) and `ConsoleMask` (7.2.5) determine which events will appear in the file and on the console, respectively. The generated logging messages are of type `USER_UNQUALIFIED`.

The `log` statement accepts among others fixed character strings TTCN-3 constants, variables, timers, functions, templates and expressions; for a complete list please refer to the table 18 in [1]. It is allowed to pass multiple arguments to a single `log` statement, separated by commas.

The TTCN-3 standard does not specify how logging information should be presented. The following sections describe how TITAN implemented logging.

The arguments of the TTCN-3 statement `action` are handled according to the same rules as `log`.

### 4.8.1 Literal Free Text String

Strings entered between quotation marks (")<sup>9</sup> and the results of special macros given in section 4.20 in the argument of the `log` statement are verbatim copied to the log. The escape sequences given in Table 4 are interpreted and the resulting non-printable characters (such as newlines, tabulators, etc.) will influence the printout.

Example:

```
log("foo\nbar");//The log printout will look like this:  
12:34:56.123456 foo  
bar
```

### 4.8.2 TTCN-3 Values and Templates

Literal values, referenced values or templates, wildcards, compound values, in-line (modified) templates, etc. (as long as the type of the expression is unambiguous) are discussed in this section.

These values are printed into the log using TTCN-3 Core Language syntax so that the printout can be simply copied into a TTCN-3 module to initialize an appropriate constant/variable/template, etc.

In case of (universal) `charstring` values the delimiter quotation marks (") are printed and the embedded non-printable characters are substituted with the escape sequences in the first 9 rows of Table 4. All other non-printable characters are displayed in the TTCN-3 quadruple notation.

---

<sup>9</sup> Former versions of the TTCN-3 standard allowed only this construct.

Prepared (Subject resp) ETHBAAT Jenő Balasko		No. 2/198 17-CRL 113 200/5 Uen		
Approved (Document resp) ETHLEL Elemer Lelik	Checked ETHGRY	Date 2015-05-15	Rev C	Reference

If the argument refers to a constant of type `charstring`, the actual value is not substituted to yield a literal string.

Example:

```
const charstring c_string := "foo\nbar\000";
log(c_string);
//The log printout will look like this:
12:34:56.123456 "foo\nbar" & char(0, 0, 0, 0)
```

### 4.8.3 Built-in Function `match()`

For the built-in `match()` function the printout will contain the detailed matching process field-by-field (similarly to the failed `receive` statements) instead of the Boolean result.

This rule is applied only if the `match()` operation is the top-level expression to be logged, see the example below:

```
// this will print the detailed matching process
log(match(v_myvalue, t_template));
// this will print only a Boolean value (true or false)
log(not not match(v_myvalue, t_template));
```

All the other predefined and user-defined functions with actual arguments will print the return value of the function into the log according to the TTCN-3 standard.

### 4.8.4 Special TTCN-3 Objects

If the argument refers to a TTCN-3 `port`, `timer` or array (slice) of the above, then the actual properties of the TTCN-3 object is printed into the log.

For ports the name and the state of the port is printed.

In case of timers the name of the timer, the default duration, the current state (`inactive`, `started` or `expired`), the actual duration and the elapsed time (if applicable) is printed in a structured form.

## 4.9 Value Returning `done`

The compiler allows starting TTCN-3 functions having return type on PTCs. Those functions must have the appropriate `runs on` clause. If such a function terminates normally on the PTC, the returned value can be matched and retrieved in a `done` operation. The compiler allows a `done` operation to have an optional template argument and an optional value redirect with the following rules:

- The syntax of the template and value redirect is identical with that of the `receive` operation.
- The type of the template and the variable used in value redirect shall be identical.

Prepared (Subject resp) ETHBAAT Jeno Balasko		No. 2/198 17-CRL 113 200/5 Uen		
Approved (Document resp) ETHLEL Elemer Lelik	Checked ETHGRY	Date 2015-05-15	Rev C	Reference

- If the value redirect is present then the template must also be present. That is, it is allowed to use a `done` statement with a template, but without a value redirect. A value redirect without a template is not allowed.
- The return type shall be a TTCN-3 type marked with the following attribute: `with { extension "done" }`. It is allowed to mark and use several types in `done` statements within one test suite. If the type to be used is defined in ASN.1 then a type alias shall be added to one of the TTCN-3 modules with the above attribute.
- The type of the template or variable must be visible from the module where the `done` statement is used.
- Only those `done` statements can have a template or a value redirect, or both that refer to a specific PTC component reference. That is, it is not allowed to use this construct with `any component.done` or `all component.done`.

Such `done` statement is successful if all the conditions below are fulfilled:

- The corresponding PTC has terminated.
- The function that was started on the PTC has normally terminated. That is, the PTC was stopped neither by itself nor by other component and no dynamic test case error occurred.
- The return type of the function that was started on the PTC is identical to the type of the template used in the `done` statement.
- The value returned by the function on the PTC matches the given template.

If the `done` operation was successful and the value redirect is present the value returned by the PTC is stored in the given variable or variable field.

The returned value can be retrieved from `alive` PTCs, too. In this case the `done` operation always refers to the return value of the lastly started behavior function of the PTC. Starting a new function on the PTC discards the return value of the previous function automatically (i.e. it cannot be retrieved or matched after the start component operation anymore).

Prepared (Subject resp) ETHBAAT Jeno Balasko		No. 2/198 17-CRL 113 200/5 Uen		
Approved (Document resp) ETHLEL Elemer Lelik	Checked ETHGRY	Date 2015-05-15	Rev C	Reference

**Example:**

```
type integer MyReturnType with { extension "done" };

function ptcBehavior() runs on MyCompType return MyReturnType
{
    return 123;
}

testcase myTestCase() runs on AnotherCompType

{
    var MyReturnType myVar;
    var MyCompType ptc := MyCompType.create;
    ptc.start(ptcBehavior());
    ptc.done(MyReturnType : ?) -> value myVar;
    // myVar will contain 123
}
```

## 4.10 Dynamic Templates

Dynamic templates (template variables, functions returning templates and passing template variables by reference) are now parts of the TTCN-3 Core Language standard ([\[1\]](#)). These constructs have been added to the standard with the same syntax and semantics as they were supported in this Test Executor. Thus dynamic templates are not considered language extensions anymore.

However, there is one extension compared to the supported version of Core Language. Unlike the standard, the compiler and the run-time environment allow the external functions to return templates.

**Example:**

```
// this is not valid according to the standard
external function MyExtFunction() return template octetstring;
```

## 4.11 Template Module Parameters

The compiler accepts template module parameters by inserting an optional “template” keyword into the standard modulepar syntax construct between the modulepar keyword and the type reference. The extended BNF rule:

ModuleParDef ::= “modulepar” (ModulePar | (“{“MultiTypedModuleParList “}”))  
ModulePar ::= [**“template”**] Type ModuleParList

**Example:**

```
modulepar template charstring mp_tstr1 := ( “a” .. “f”) ifpresent
modulepar template integer mp_tint := complement (1,2,3)
```

Prepared (Subject resp) ETHBAAT Jeno Balasko		No. 2/198 17-CRL 113 200/5 Uen		
Approved (Document resp) ETHLEL Elemer Lelik	Checked ETHGRY	Date 2015-05-15	Rev C	Reference

## 4.12 Predefined Functions

The built-in predefined functions `ispresent`, `ischosen`, `lengthof` and `sizeof` are applicable not only to value-like language elements (constants, variables, etc.), but template-like entities (templates, template variables, template parameters) as well. If the function is allowed to be called on a value of a given type it is also allowed to be called on a template of that type with the meaning described in the following subchapters.

Note: "dynamic test case error" does not necessarily denote here an error situation: it may well be a regular outcome of the function.

### 4.12.1 `sizeof`

The function `sizeof` is applicable to templates of `record`, `set`, `record of`, `set of` and `objid` types. The function is applicable only if the `sizeof` function gives the same result on all values that match the template.<sup>10</sup> In case of `record of` and `set of` types the length restrictions are also considered. Dynamic test case error occurs if the template can match values with different sizes or the length restriction contradicts the number of elements in the template body.

Examples:

```
type record of integer R;  
type set S { integer f1, bitstring f2 optional, charstring f3 optional }  
template R tr_1 := { 1, permutation(2, 3), ? }  
template R tr_2 := { 1, *, (2, 3) }  
template R tr_3 := { 1, *, 10 } length(5)  
template R tr_4 := { 1, 2, 3, * } length(1..2)  
template S tr_5 := { f1 := (0..99), f2 := omit, f3 := ? }  
template S tr_6 := { f3 := *, f1 := 1, f2 := '00'B ifpresent }  
template S tr_7 := ({ f1 := 1, f2 := omit, f3 := "ABC" },  
                  { f1 := 2, f3 := omit, f2 := '1'B })  
template S tr_8 := ?
```

```
//sizeof(tr_1) → 4  
//sizeof(tr_2) → error  
//sizeof(tr_3) → 5  
//sizeof(tr_4) → error  
//sizeof(tr_5) → 2  
//sizeof(tr_6) → error  
//sizeof(tr_7) → 2  
//sizeof(tr_8) → error
```

### 4.12.2 `ispresent`

The predefined function `ispresent` has been extended; its parameter can now be any valid `TemplateInstance`. It is working according to the following ETSI CRs: <http://t-ort.etsi.org/view.php?id=5934> and <http://t-ort.etsi.org/view.php?id=5936>

<sup>10</sup> The `sizeof` function returns the number of elements in case of `record of` and `set of` values. In case of `record` and `set` values the number of mandatory fields plus the optional fields that are present in the actual value is returned.

Prepared (Subject resp) ETHBAAT Jenö Balasko		No. 2/198 17-CRL 113 200/5 Uen		
Approved (Document resp) ETHLEL Elemer Lelik	Checked ETHGRY	Date 2015-05-15	Rev C	Reference

### 4.12.3 `oct2unichar`

The function `oct2unichar` (in `octetstring` `invalue`, in `charstring` `string_encoding` := "UTF-8") return universal `charstring` converts an `octetstring` `invalue` to a universal `charstring` by use of the given `string_encoding`. The octets are interpreted as mandated by the standardized mapping associated with the given `string_encoding` and the resulting characters are appended to the returned value. If the optional `string_encoding` parameter is omitted, the default value "UTF-8".

The following values are allowed as `string_encoding` actual parameters: UTF8, UTF-16, UTF-16BE, UTF-16LE, UTF-32, UTF-32BE, UTF-32LE.

DTE occurs if the `invalue` does not conform to UTF standards. The `oct2unichar` checks if the Byte Order Mark (BOM) is present. If not a warning will be appended to the log file. `oct2unichar` will decode the `invalue` even in absence of the BOM.

Any code unit greater than 0x10FFFF is ill-formed.

UTF-32 code units in the range of 0x0000D800 – 0x0000DFFF are ill-formed.

UTF-16 code units in the range of 0xD800 – 0xDFFF are ill-formed.

UTF-8 code units in the range of 0xD800 – 0xDFFF are ill-formed.

#### EXAMPLE:

```
oct2unichar('C384C396C39CC3A4C3B6C3BC'O) = "ÄÖÜäöü";  
oct2unichar('00C400D600DC00E400F600FC'O, "UTF-16LE") = "ÄÖÜäöü";
```

Prepared (Subject resp) ETHBAAT Jenö Balasko		No. 2/198 17-CRL 113 200/5 Uen		
Approved (Document resp) ETHLEL Elemer Lelik	Checked ETHGRY	Date 2015-05-15	Rev C	Reference

#### 4.12.4 `unichar2oct`

The function `unichar2oct` (in universal charstring `invalue`, in charstring `string_encoding := "UTF-8"`) return `octetstring` converts a universal charstring `invalue` to an `octetstring`. Each octet of the `octetstring` will contain the octets mandated by mapping the characters of `invalue` using the standardized mapping associated with the given `string_encoding` in the same order as the characters appear in `inpar`. If the optional `string_encoding` parameter is omitted, the default encoding is "UTF-8".

The following values are allowed as `string_encoding` actual parameters: UTF-8, UTF-8 BOM, UTF-16, UTF-16BE, UTF-16LE, UTF-32, UTF-32BE, UTF-32LE.

The function `unichar2oct` adds the Byte Order Mark (BOM) to the beginning of the `octetstring` in case of UTF-16 and UTF-32 encodings. The `remove_bom` function helps to remove it, if it is not needed. The presence of the BOM is expected at the inverse function `oct2unichar` because the coding type (without the BOM) can be detected only in case of UTF-8 encoded `octetstring`. By default UTF-8 encoding does not add the BOM to the `octetstring`, however UTF-8 BOM encoding can be used to add it.

DTE occurs if the `invalue` does not conform to UTF standards.

Any code unit greater than 0x10FFFF is ill-formed.

#### EXAMPLE:

```
unichar2oct("ÄÖÜäöü") = 'EFBBBFC384C396C39CC3A4C3B6C3BC'O;  
unichar2oct("ÄÖÜäöü", "UTF-16LE") = 'FFFE00C400D600DC00E400F600FC'O;
```

Prepared (Subject resp) ETHBAAT Jenö Balasko		No. 2/198 17-CRL 113 200/5 Uen		
Approved (Document resp) ETHLEL Elemer Lelik	Checked ETHGRY	Date 2015-05-15	Rev C	Reference

#### 4.12.5 `get_stringencoding`

The function `get_stringencoding` (in `octetstring` `encoded_value`) return `charstring` identifies the encoding of the `encoded_value`. The following return values are allowed as `charstring`: ASCII, UTF-8, UTF-16BE, UTF-16LE, UTF-32BE, UTF-32LE.

If the type of encoding could not be identified, it returns the value: `<unknown>`

##### EXAMPLE:

```
var octetstring invaline := 'EFBBBFC384C396C39CC3A4C3B6C3BC'O;  
var charstring codingtype := get_stringencoding(invaline);  
the resulting codingtype is "UTF-8"
```

#### 4.12.6 `remove_bom`

The function `remove_bom` (in `octetstring` `encoded_value`) return `octetstring` strips the BOM if it is present and returns the original `octetstring` otherwise.

##### EXAMPLE:

```
var octetstring invaline := 'EFBBBFC384C396C39CC3A4C3B6C3BC'O;  
var octetstring nobom := remove_bom(invaline);  
the resulting nobom contains: 'C384C396C39CC3A4C3B6C3BC'O;
```

### 4.13 Additional Predefined Functions

In addition to standardized TTCN-3 predefined functions given in Annex C of [\[1\]](#) and Annex B of [\[3\]](#) the following built-in conversion functions are supported by our compiler and run-time environment:

#### 4.13.1 `str2bit`

The function `str2bit` (`charstring` `value`) return `bitstring` converts a `charstring` value to a `bitstring`, where each character represents the value of one bit in the resulting `bitstring`. Its argument may contain the characters "0" or "1" only, otherwise the result is a dynamic test case error.

**Note:** This function is the reverse of the standardized `bit2str`.

Example:

Prepared (Subject resp) ETHBAAT Jenő Balasko		No. 2/198 17-CRL 113 200/5 Uen		
Approved (Document resp) ETHLEL Elemer Lelik	Checked ETHGRY	Date 2015-05-15	Rev C	Reference

```
str2bit ("1011011100") = '1011011100'B
```

#### 4.13.2 **str2hex**

The function `str2hex (charstring value)` return `hexstring` converts a `charstring` value to a `hexstring`, where each character in the character string represents the value of one hexadecimal digit in the resulting `hexstring`. The incoming character string may contain any number of characters. A dynamic test case error occurs if one or more characters of the `charstring` are outside the ranges "0" .. "9", "A" .. "F" and "a" .. "f".

**Note:** This function is the reverse of the standardized `hex2str`.

Example:

```
str2hex ("1D7") = '1D7'H
```

#### 4.13.3 **float2str**

The function `float2str (float value)` return `charstring` converts a `float` value to a `charstring`. If the input is zero or its absolute value is between  $10^{-4}$  and  $10^{10}$ , the decimal dot notation is used in the output with 6 digits in the fraction part. Otherwise the exponential notation is used with automatic (at most 6) digits precision in the mantissa.

Example:

```
float2str (3.14) = "3.140000"
```

#### 4.13.4 **unichar2char**

The function `unichar2char (universal charstring value)` return `charstring` converts a `universal charstring` value to a `charstring`. The elements of the input string are converted one by one. The function only converts universal characters when the conversion result lies between 0 and 127 (that is, the result is an ISO 646 character).

Note: the inverse conversion is implicit, that is, the `charstring` values are converted to `universal charstring` values automatically, without the need for a conversion function.

Example:

```
unichar2char(char(0,0,0,64)) = "@"
```

#### 4.13.5 **log2str**

The function `log2str` can be used to log into `charstring` instead of the log file.

Prepared (Subject resp) ETHBAAT Jeno Balasko		No. 2/198 17-CRL 113 200/5 Uen		
Approved (Document resp) ETHLEL Elemer Lelik	Checked ETHGRY	Date 2015-05-15	Rev C	Reference

**Syntax:**

```
log2str (...) return charstring
```

This function can be parameterized in the same way as the `log` function, it returns a `charstring` value which contains the log string for all the provided parameters, but it does not contain the timestamp, severity and call stack information, thus the output does not depend on the runtime configuration file. The parameters are interpreted the same way as they are in the `log` function: their string values are identical to what the log statement writes to the log file. The extra information (timestamp, severity, call stack) not included in the output can be obtained by writing external functions which use the runtime's `Logger` class to obtain the required data.

**4.13.6 testcasename**

The function `testcasename` returns the unqualified name of the actually executing test case. When it is called from the control part and no test case is being executed, it returns the empty string.

**Syntax:**

```
testcasename () return charstring
```

**4.13.7 isbound**

The `isbound` function behaves identically to the `isvalue` function with the following exception: it returns true for a record-of value which contains both initialized and uninitialized elements.

```
type record of integer rint;  
var rint r_u; // uninitialized  
isvalue(r_u); // returns false  
isbound(r_u); // returns false also  
//lengthof(r_u) would cause a dynamic testcase error
```

```
var rint r_0 := {} // zero length  
isvalue(r_3); // returns true  
isbound(r_3); // returns true  
lengthof(r_3); // returns 0
```

```
var rint r_3 := { 0, -, 2 } // has a "hole"  
isvalue(r_3); // returns false  
isbound(r_3); // returns true  
lengthof(r_3); // returns 3
```

```
var rint r_3full := { 0, 1, 2 }  
isvalue(r_3full); // returns true  
isbound(r_3full); // returns true  
lengthof(r_3full); // returns 3
```

Prepared (Subject resp) ETHBAAT Jenő Balasko		No. 2/198 17-CRL 113 200/5 Uen		
Approved (Document resp) ETHLEL Elemer Lelik	Checked ETHGRY	Date 2015-05-15	Rev C	Reference

The introduction of `isbound` permits TTCN-3 code to distinguish between `r_u` and `r_3`; `isvalue` alone cannot do this (it returns false for both).

Syntax:

```
isbound (in template any_type i) return boolean;
```

#### 4.13.8 `ttcn2string`

Syntax:

```
ttcn2string(in <TemplateInstance> ti) return charstring
```

This predefined function returns its parameter's value in a string which is in TTCN-3 syntax. The returned string has legal ttcn-3 with a few exceptions such as unbound values. Unbound values are returned as "-", which can be used only as fields of assignment or value list notations, but not as top level assignments (e.g. `x:=` is illegal). Differences between the output format of `ttcn2string()` and `log2str()`:

Value/template	<code>log2str()</code>	<code>ttcn2string()</code>
Unbound value	"<unbound>"	"-"
Uninitialized template	"<uninitialized template>"	"-"
Enumerated value	name (number)	name

#### 4.13.9 `string2ttcn`

Syntax:

```
string2ttcn(in charstring ttcn_str, inout <reference> ref)
```

This predefined function does not have a return value, thus it is a statement. Any error in the input string will cause an exception that can be caught using `@try - @catch` blocks. The message string of the exception contains the exact cause of the error. There might be syntax and semantic errors. This function uses the module parameter parser of the TITAN runtime, it accepts the same syntax as the module parameters of the configuration file. Check the documentation chapters for the module parameters section. There are differences between the ttcn-3 syntax and the configuration file module parameters syntax, these are described in the documentation chapter of the module parameters. The second parameter must be a reference to a value or template variable. Example code:

Prepared (Subject resp) ETHBAAT Jenö Balasko		No. 2/198 17-CRL 113 200/5 Uen		
Approved (Document resp) ETHLEL Elemer Lelik	Checked ETHGRY	Date 2015-05-15	Rev C	Reference

```
type record MyRecord { integer a, boolean b }
...
var template MyRecord my_rec
@try {
    string2ttcn("complement ({1,?},{(1,2,3),false}) ifpresent", my_rec)
    log(my_rec)
}
@catch (err_str) {
    log("string2ttcn() failed: ", err_str)
}
```

The log output will look like this:

complement ({ a := 1, b := ? }, { a := (1, 2, 3), b := false }) ifpresent

#### 4.13.10 encode\_base64

Syntax:

```
encode_base64(in octetstring ostr, in boolean
use_linebreaks := false) return charstring
```

The function `encode_base64 (in octetstring ostr, in boolean use_linebreaks := false) return charstring` converts an octetstring `ostr` to a charstring. The charstring will contain the Base64 representation of `ostr`. The `use_linebreaks` parameter adds newlines after every 76 output characters, according to the MIME specs, if it is omitted, the default value is false.

EXAMPLE:

```
encode_base64('42617365363420656E636F64696E6720736368656D65'O) ==
"QmFzZTY0IGVuY29kaW5nIHNjaGVtZQ=="
```

#### 4.13.11 decode\_base64

Syntax:

```
decode_base64(in charstring str) return octetstring
```

The function `decode_base64 (in charstring str) return octetstring` converts a charstring `str` encoded in Base64 to an octetstring. The octetstring will contain the decoded Base64 string of `str`.

EXAMPLE:

```
decode_base64("QmFzZTY0IGVuY29kaW5nIHNjaGVtZQ==") ==
'42617365363420656E636F64696E6720736368656D65'O
```

Prepared (Subject resp) ETHBAAT Jeno Balasko		No. 2/198 17-CRL 113 200/5 Uen		
Approved (Document resp) ETHLEL Elemer Lelik	Checked ETHGRY	Date 2015-05-15	Rev C	Reference

#### 4.14 Exclusive Boundaries in Range Subtypes

The boundary values used to specify range subtypes can be preceded by an exclamation mark. By using the exclamation mark the boundary value itself can be excluded from the specified range. For example integer range (!0..!10) is equivalent to range (1..9). In case of float type open intervals can be specified by using excluded boundaries, for example (0.0..!1.0) is an interval which contains 0.0 but does not contain 1.0.

#### 4.15 Special Float Values Infinity and `not_a_number`

The keyword infinity (which is also used to specify value range and size limits) can be used to specify the special float values `-infinity` and `+infinity`, these are equivalent to `MINUS-INFINITY` and `PLUS-INFINITY` used in ASN.1. A new keyword `not_a_number` has been introduced which is equivalent to `NOT-A-NUMBER` used in ASN.1. The special values cannot be used in arithmetic operations. The special value `not_a_number` cannot be used in a float range subtype because it's an unordered value, but can be added as a single value, for example subtype (0.0 .. infinity, `not_a_number`) contains all positive float values and the `not_a_number` value.

#### 4.16 TTCN-3 Preprocessing

Preprocessing of the TTCN-3 files with a C preprocessor is supported by the compiler. External preprocessing is used: the Makefile Generator generates a `Makefile` which will invoke the C preprocessor to preprocess the TTCN-3 files with the suffix `.ttcnpp`. The output of the C preprocessor will be generated to an intermediate file with the suffix `.ttcn`. The intermediate files contain the TTCN-3 source code and line markers. The compiler can process these line markers along with TTCN-3. If the preprocessing is done with the `-P` option<sup>11</sup>, the resulting code will not contain line markers; it will be compatible with any standard TTCN-3 compiler. The compiler will use the line markers to give almost<sup>12</sup> correct error or warning messages, which will point to the original locations in the `.ttcnpp` file. The C preprocessor directive `#include` can be used in `.ttcnpp` files; the Makefile Generator will treat all files with suffix `.ttcnin` as TTCN-3 include files. The `.ttcnin` files will be added to the Makefile as special TTCN-3 include files which will not be translated by the compiler, but will be checked for modification when building the test suite.

Extract from the file `Example.ttcnpp`:

<sup>11</sup> `-P` is valid for GCC. Preprocessors of other compilers may use a different switch.

<sup>12</sup> A hint is given to the line number.

Prepared (Subject resp) ETHBAAT Jenö Balasko		No. 2/198 17-CRL 113 200/5 Uen		
Approved (Document resp) ETHLEL Elemer Lelik	Checked ETHGRY	Date 2015-05-15	Rev C	Reference

```
module Example {  
  function func()  
  {  
    #ifdef DEBUG  
      log("Example: DEBUG");  
    #else  
      log("Example: RELEASE");  
    #endif  
  }  
  ...  
}
```

The output is a preprocessed intermediate file `Example.ttcn`. The resulting output from the above code:

```
...  
# 1 "Example.ttcnpp"  
module Example {  
  function func()  
  {  
    log("Example: RELEASE");  
  }  
}
```

The line marker (`# 1 "Example.ttcnpp"`) tells the compiler what the origin of the succeeding code is.

## 4.17 Parameter List Extensions

In addition to standardized TTCN-3 parameter handling described in 5.4.2 of [\[1\]](#) TITAN also supports the mixing of list notation and assignment notation in an actual parameter list.

### 4.17.1 Missing Named and Unnamed Actual Parameters

To facilitate handling of long actual parameter lists in the TITAN implementation, the actual parameter list consists of two optional parts: an unnamed part followed by a named part, in this order. In the actual parameter list a value must be assigned to every mandatory formal parameter either in the named part or in the unnamed part. (Mandatory parameter is one without default value assigned in the formal parameter list.) Consequently, the unnamed part, the named part or both may be omitted from the actual parameter list. Omitting the named part from the actual parameter lists provides backward compatibility with the standard notation.

The named and unnamed parts are separated by a comma as are the elements within both lists. It is not allowed to assign value to a given formal parameter in both the named and the unnamed part of the actual parameter list.

There can be at most one unnamed part, followed by at most one named part. Consequently, an unnamed actual parameter may not follow a named parameter.

Named actual parameters must follow the same relative order as the formal parameters. It is not allowed to specify named actual parameters in an arbitrary order.

Prepared (Subject resp) ETHBAAT Jenö Balasko		No. 2/198 17-CRL 113 200/5 Uen		
Approved (Document resp) ETHLEL Elemer Lelik	Checked ETHGRY	Date 2015-05-15	Rev C	Reference

## Examples

The resulting parameter values are indicated in brackets in the comments:

```
function myFunction(integer p_par1, boolean p_par2 := true) { ... }
control {
  // the actual parameter list is syntactically correct below:
  myFunction(1, p_par2 := false);           // (1, false)
  myFunction(2);                           // (2, true)
  myFunction(p_par1 := 3, p_par2 := false); // (3, false)
  // the actual parameter list is syntactically erroneous below:
  myFunction(0, true, -);                   // too many parameters
  myFunction(1, p_par1 := 1);               // p_par1 is given twice
  myFunction();                             // no value is assigned to mandatory p_par1
  myFunction(p_par2 := false, p_par1 := 3); // out of order
  myFunction(p_par2 := false, 1);           // unnamed part cannot follow
                                           // named part
}
```

## 4.18 function, altstep and testcase References

Although TITAN supports the behaviour type package [\[5\]](#) of the TTCN-3 standard, but this feature was included in the standard with a different syntax.

It is allowed to create TTCN-3 types of functions, altsteps and testcases. Values, for example variables, of such types can carry references to the respective TTCN-3 definitions. To facilitate reference using, three new operations (`refers`, `derefers` and `apply`) were introduced. This new language feature allows to create generic algorithms in TTCN-3 with late binding, (i.e. code in which the function to be executed is specified only at runtime).

## 4.19 Function Types with a RunsOn\_self Clause

A function type or an altstep type, defined with a standard `runs on` clause, can use all constants, variables, timers and ports given in the component type definition referenced by the `runs on` clause (see chapter 16 of [\[1\]](#)).

A function type or an altstep type, defined with the TITAN-introduced `runs on self` clause, similarly, makes use of the resources of a component type; however, the component type in question is not given in advance. When an altstep or a function is called via a function variable, that is, a reference, using the `apply` operation, it can use the resources defined by the component type indicated in the `runs on` clause of the actually referenced function or altstep.

The “runs on self” construct is permitted only for function and altstep types. Any actual function or altstep must refer to a given component type name in their `runs on` clause.

A variable with type of function type is called a **function variable**. Such variables can contain references to functions or altsteps. At function variable assignment, component type compatibility checking is performed with respect to the component context of the assignment statement and the “runs on”

Prepared (Subject resp) ETHBAAT Jenö Balasko		No. 2/198 17-CRL 113 200/5 Uen		
Approved (Document resp) ETHLEL Elemer Lelik	Checked ETHGRY	Date 2015-05-15	Rev C	Reference

clause of the assigned function or `altstep`. When the `apply()` operator is applied to a function variable, no compatibility checking is performed; see section 0 for an example.

The rationale for this distinction is the following: due to type compatibility checking at the time of value assignment to the function variable, the TTCN-3 environment can be sure that any non-`null` value of the variable is a function reference that is component-type-compatible with that component that is actually executing the code using the `apply()` operator.

As a consequence of this, it is forbidden to use values of function variables as arguments to the TTCN-3 operators `start()` or `send()`.

Example of using the clause `runs on self` in a library

A component type may be defined as an extension of another component type (using the standard `extends` keyword mentioned in chapter 6.2.10.2 of [1]). The effect of this definition is that the extended component type will implicitly contain all constant, variable, port and timer definitions from the parent type as well. In the example below, the component type `User_CT` aggregates its own constant, variable, port and timer definitions (resources) with those defined in the component type `Library_CT` (see line a).

The library developer writes a set of library functions that have a `runs on Library_CT` clause (see line h). Such library functions may offer optional references to other functions that are supposed to be specified by the user of the library (see line e). We say in this case that the library function may call user-provided **callback functions** via function variables. These function variables must have a type specified; optionally with a `runs on` clause. If this `runs on` clause refers to an actual component type name, then this actual type name must be known at the time of writing the library.

Library functions that `runs on Library_CT` can run on other component types as well, provided that the actual component type is compatible with `Library_CT` (see chapter 6.3.3 of [1]). An obvious design goal for the library writer is to permit references to any callback function that has a component-type-compatible `runs on` clause. However, the cardinality of compatible component types is infinitely large; therefore, they **cannot** be explicitly referenced by the function type definitions of the library.

The “runs on self” concept provides a remedy for this contradiction and allows conceiving library components prepared to take up user-written “plug-ins”.

In the code excerpt below, function `f_LibraryFunction` (which has the clause `runs on Library_CT`) uses the function reference variable `v_callbackRef_self` (defined in `Library_CT`). The function `f_MyCallbackFunction` (see line b) has a `runs on User_CT` clause.

Prepared (Subject resp) ETHBAAT Jeno Balasko		No. 2/198 17-CRL 113 200/5 Uen		
Approved (Document resp) ETHLEL Elemer Lelik	Checked ETHGRY	Date 2015-05-15	Rev C	Reference

User\_CT (see line a) extends Library\_CT, therefore it is suitable for running library function with runs on Library\_CT clause, for example.

When the assignment to the function variable v\_CallbackRef\_self is performed (see line c) inside f\_MyUserFunction (that is, inside the context User\_CT), then compatibility checking is performed. Since User\_CT is compatible with Library\_CT, the assignment is allowed.

Direct call to f\_MyCallbackFunction() with runs on User\_CT from a runs on Library\_CT context (see line g) would cause semantic error according to the TTCN-3 language. However, calling the function via v\_CallbackRef\_self is allowed (see line d).

Prepared (Subject resp) ETHBAAT Jeno Balasko		No. 2/198 17-CRL 113 200/5 Uen		
Approved (Document resp) ETHLEL Elemer Lelik	Checked ETHGRY	Date 2015-05-15	Rev C	Reference

The compiler and the run-time environment support the following non-standard macro notation in TTCN-3 modules. All TTCN-3 macros consist of a percent (%) character followed by the macro identifier. Macro identifiers are case sensitive. The table below summarizes the available macros and their meaning. Macro identifiers not listed here are reserved for future extension.

Table 5 TTCN-3 macros

Macro	Meaning
%moduleId	name of the TTCN-3 module
%definitionId	name of the top-level TTCN-3 definition
%testCaseId	name of the test case that is currently being executed
%fileName	name of the TTCN-3 source file
%lineNumber	number of line in the source file

The following rules apply to macros:

- All macros are substituted with a value of type `charstring`. They can be used as operands of complex expressions (concatenation, comparison, etc.).
- All macros except %testCaseId are evaluated during compilation and they can be used anywhere in the TTCN-3 module.
- Macro %testCaseId is evaluated at runtime. It can be used only within functions and altsteps that are being run on test components (on the MTC or PTCs) and within testcases. It is not allowed to use macro %testCaseId in the module control part. If a function or altstep that contains macro %testCaseId is called directly from the control part the evaluation of the macro results in a dynamic test case error.
- The result of macro %testCaseId is not a constant thus it cannot be used in the value of TTCN-3 constants. It is allowed only in those contexts where TTCN-3 variable references are permitted.
- Macro %definitionId is always substituted with the name of the top-level module definition that it is used in.<sup>13</sup> For instance, if the macro appears in a constant that is defined within a function then the macro will be substituted with the function's name rather than the one of the constant. When used within the control part macro %definitionId is substituted with the word "control".

---

<sup>13</sup> TTCN-3 groups are not definitions.

Prepared (Subject resp) ETHBAAT Jenő Balasko		No. 2/198 17-CRL 113 200/5 Uen		
Approved (Document resp) ETHLEL Elemer Lelik	Checked ETHGRY	Date 2015-05-15	Rev C	Reference

- Macro `%fileName` is substituted with the name of the source file in the same form as it was passed to the compiler. This can be a simple file name, a relative or an absolute path name.
- The result of macro `%lineNumber` is always a string that contains the current line number as a decimal number. Numbering of lines starts from 1. All lines of the input file (including comments and empty lines) are counted. When it needs to be used in an integer expression a conversion is necessary: `str2int(%lineNumber)`. The above expression is evaluated during compilation without any runtime performance penalty.
- Source line markers are considered when evaluating macros `%fileName` and `%lineNumber`. In preprocessed TTCN-3 modules the macros are substituted with the original file name and line number that the macro comes from provided that the preprocessor supports it.
- When macros are used in `log()` statements, they are treated like literal strings rather than charstring value references. That is, quotation marks around the strings are not used and special characters within them are not escaped in the log file.
- For compatibility with the C preprocessor the compiler also recognizes the following C style macros: `__FILE__` is identical to `%fileName` and `__LINE__` is identical to `str2int(%lineNumber)`.
- Macros are not substituted within quotation marks (i.e. within string literals and attributes).
- The full power of TTCN-3 macros can be exploited in combination with the C preprocessor.

Prepared (Subject resp) ETHBAAT Jenő Balasko		No. 2/198 17-CRL 113 200/5 Uen		
Approved (Document resp) ETHLEL Elemer Lelik	Checked ETHGRY	Date 2015-05-15	Rev C	Reference

### Example:

```

module M {
    // the value of c_MyConst will be "M"
    const charstring c_MyConst := %moduleId;
    // MyTemplate will contain 28
    template integer t_MyTemplateWithVeryLongName := lengthof(%definitionId);
    function f_MyFunction() {
        // the value of c_MyLocalConst1 will be "f_MyFunction"
        const charstring c_MyLocalConst1 := %definitionId;
        // the value of c_MyLocalConst2 will be "%definitionId"
        const charstring c_MyLocalConst2 := "%definitionId";
        // the value of c_MyLocalConst3 will be "12"
        const charstring c_MyLocalConst3 := %lineNumber; //This is line 12
        // the value of c_MyLocalConst4 will be 14
        const integer c_MyLocalConst4 := str2int(%lineNumber); //This is line 14
        // the line below is invalid because %testCaseId is not a constant
        const charstring c_MyInvalidConst := %testCaseId;
        // this is valid, of course
        var charstring v_MyLocalVar := %testCaseId;
        // the two log commands below give different output in the log file
        log("function: ", %definitionId, " testcase: ", %testCaseId);
        // printout: function: f_MyFunction testcase: tc_MyTestcase
        log("function: ", c_MyLocalConst1, " testcase: ", v_MyLocalVar);
        // printout: function: "f_MyFunction" testcase: "tc_MyTestcase"
    }
}

```

## 4.21 Component Type Compatibility

The ETSI standard defines type compatibility of component types for component reference values and for functions with "runs on" clause. In order to be compatible, both component types are required to have identical definitions (cf. [\[1\]](#), chapter 6.3.3).

**Note:** Compatibility is an asymmetric relation, if component type B is compatible with component type A, the opposite is not necessarily true. (E.g., component type B may contain definitions absent in component type A.)

All definitions from the parent type are implicitly contained when the keyword `extends` appears in the type definition (cf. [\[1\]](#), chapter 6.2.10.2) and so the required identity of the type definitions is ensured. The compiler considers component type B to be compatible with A if B has an `extends` clause, which contains A or a component type that is compatible with A.

### Example:

```

type component A { var integer i; }
type component B extends A {
    // extra definitions may be added here
}

```

In order to provide support for existing TTCN-3 code (e.g. standardized test suites) it is allowed to explicitly signal the compatibility relation between component types using a special `extension` attribute. Using such attributes shall be avoided in newly written TTCN-3 modules. Combining component type inheritance and the attribute `extension` is possible, but not recommended.

Prepared (Subject resp) ETHBAAT Jenő Balasko		No. 2/198 17-CRL 113 200/5 Uen		
Approved (Document resp) ETHLEL Elemer Lelik	Checked ETHGRY	Date 2015-05-15	Rev C	Reference

Thus, the compiler considers component type B to be compatible with A if B has an `extension` attribute that points to A as base component type and all definitions of A are present and identical in B.

```
type component A { var integer i; }
type component B {
    var integer i; // definitions of A must be repeated
    var octetstring o; // new definitions may be added
} with {
    extension "extends A"
}
```

#### 4.21.1 Implementation Restrictions

The list of definitions shared with different compatible component types shall be distinct. If component type Z is compatible with both X and Y and neither X is compatible with Y nor Y is compatible with X then X and Y shall not have definitions with identical names but different origin. If both X and Y are compatible with component type C then all definitions in X and Y which are originated from C are inherited by Z on two paths.

Example: According to the standard component type Z should be compatible with both X and Y, but the compatibility relation cannot be established because X and Y have a definition with the same name.

```
type component X { timer T1, T2; }
type component Y { timer T1, T3; }
type component Z { timer T1, T2, T3; }
    with { extension "extends X, Y" }
    // invalid because the origin of T1 is ambiguous
```

The situation can be resolved by introducing common ancestor C for X and Y, which holds the shared definition.

```
type component C { timer T1; }
type component X { timer T1, T2; } with { extension "extends C" }
type component Y { timer T1, T3; } with { extension "extends C" }
type component Z {
    timer T1, // origin is C
    T2, // origin is X
    T3; // origin is Y
} with { extension "extends X, Y" }
```

Circular compatibility chains between component types are not allowed. If two component types need to be defined as identical, type aliasing must be used instead of compatibility.

The following code is invalid:

```
type component A {
    ...
    // the same definitions as in B
} with { extension "extends B" }
type component B {
    ...
    // the same definitions as in A
} with { extension "extends A" }
```

When using the non-standard extension attribute the initial values of the corresponding definitions of compatible components should be identical. The compiler does not enforce this for all cases; however, in the case of different initial values the resulting run-time behavior is undefined. If the initial values cannot be determined at compile time (module parameters) the compiler will

Prepared (Subject resp) ETHBAAT Jeno Balasko		No. 2/198 17-CRL 113 200/5 Uen		
Approved (Document resp) ETHLEL Elemer Lelik	Checked ETHGRY	Date 2015-05-15	Rev C	Reference

remain silent. In other situations the compiler may report an error or a warning.

All component types are compatible with each empty component type. Empty components are components which have neither own nor inherited definitions.

## 4.22 Implicit Message Encoding

The TTCN-3 standard [1] does not specify a standard way of data encoding/decoding. TITAN has a common C++ API for encoding/decoding; to use this API external functions are usually needed. The common solution is to define a TTCN-3 external function and write the C++ code containing the API calls. In most cases the C++ code explicitly written to an auxiliary C++ file contains only simple code patterns which call the encoding/decoding API functions on the specified data. In TITAN there is a TTCN-3 language extension which automatically generates such external functions.

Based on this automatic encoding/decoding mechanism, dual-faced ports are introduced. Dual-faced ports have an external and an internal interface and can automatically transform messages passed through them based on mapping rules defined in TTCN-3 source files. These dual-faced ports eliminate the need for simple port mapping components and thus simplify the test configuration.

### 4.22.1 Dual-faced Ports

In the TTCN-3 standard ([1]), a port type is defined by listing the allowed incoming and outgoing message types. Dual-faced ports have on the other hand two different message lists: one for the external and one for the internal interface. External and internal interfaces are given in two distinct port type definitions. The dual-faced concept is applicable to message based ports and the message based part of mixed ports.

Dual-faced port types must have `user` attribute to designate its external interface. The internal interface is given by the port type itself. A port type can be the external interface of several different dual-faced port types.

The internal interface is involved in communication operations (`send`, `receive`, etc.) and the external interface is used when transferring messages to/from other test components or the system under test. The operations `connect` and `map` applied on dual-faced ports will consider the external port type when checking the consistency of the connection or mapping.<sup>14</sup>

<sup>14</sup> This is the only point where TTCN-3 code using dual-faced ports violates the Core Language standard.

Prepared (Subject resp) ETHBAAT Jeno Balasko		No. 2/198 17-CRL 113 200/5 Uen		
Approved (Document resp) ETHLEL Elemer Lelik	Checked ETHGRY	Date 2015-05-15	Rev C	Reference

#### 4.22.1.1 Dual-faced Ports between Test Components

Dual-faced ports used for internal communication must have the attributes `internal` in addition to `user` (see section [4.2](#)). The referenced port type describing the external interface may have any attributes.

#### 4.22.1.2 Dual-faced Ports between Test Components and the SUT

The port type used as external interface must have the attribute `provider`. These dual-faced port types do not have their own test port; instead, they use the test port belonging to the external interface when communicating to SUT. Using the attribute `provider` implies changes in the Test Port API of the external interface. For details see the section “Provider port types” in [\[16\]](#).

If there are several entities within the SUT to be addressed, the dual-faced port type must have the attribute `address` in addition to `user`. In this case the external interface must have the attribute `address` too. For more details see section [4.2](#).

### 4.22.2 Type Mapping

Mapping is required between the internal and external interfaces of the dual-faced ports because the two faces are specified in different port type definitions, thus, enabling different sets of messages.

Messages passing through dual-faced ports will be transformed based on the mapping rules. Mapping rules must be specified for the outgoing and incoming directions separately. These rules are defined in the attribute `user` of the dual-faced port type.

An outgoing mapping is applied when a `send` operation is performed on the dual-faced port. The outcome of the mapping will be transmitted to the destination test component or SUT. The outgoing mappings transform each outgoing message of the internal interface to the outgoing messages of the external interface.

An incoming mapping is applied when a message arrives on a dual-faced port from a test component or the SUT. The outcome of the mapping will be inserted into the port queue and it will be extracted by the `receive` operation. The incoming mappings transform each incoming messages of the external interface to the incoming message of the internal interface.

#### 4.22.2.1 Mapping Rules

A mapping rule is an elementary transformation step applied on a message type (source type) resulting in another message type (target type). Source type and target type are not necessarily different.

Prepared (Subject resp) ETHBAAT Jeno Balasko		No. 2/198 17-CRL 113 200/5 Uen		
Approved (Document resp) ETHLEL Elemer Lelik	Checked ETHGRY	Date 2015-05-15	Rev C	Reference

Mapping rules are applied locally in both directions, thus, an error caused by a mapping rule affects the test component owning the dual-faced port, not its communication partner.

Mappings are given for each source type separately. Several mapping targets may belong to the same source type; if this is the case, all targets must be listed immediately after each other (without repeating the source type).

The following transformation rules may apply to the automatic conversion between the messages of the external and internal interfaces of a dual-faced port:

- **No conversion.**  
Applicable to any message type, this is a type preserving mapping, no value conversion is performed. Source and target types must be identical. This mapping does not have any options. For example, control or status indication messages may transparently be conveyed between the external and the internal interfaces.  
Keyword used in attribute `user` of port type definition: `simple`.
- **Message discarding.**  
This rule means that messages of the given source type will not be forwarded to the opposite interface. Thus, there is no destination type, which must be indicated by the not used symbol (-). This mapping does not have any options. For example, incoming status indication messages of the external interface may be omitted on the internal interface.  
Keyword used in attribute `user` of port type definition: `discard`.
- **Conversion using the built-in codecs.**  
Here, a corresponding encoding or decoding subroutine of the built-in codecs (for example RAW, TEXT or BER) is invoked. The conversion and error handling options are specified with the same syntax as used for the encoding/decoding functions, see section [4.22.4.2](#). Here, source type corresponds to input type and target type corresponds to output type of the encoding.  
Keyword used in attribute `user` of port type definition: `encode` or `decode`; either followed by an optional `errorbehavior`.
- **Function or external function.**  
The transformation rule may be described by an (external) function referenced by the mapping.  
The function must have the attribute `extension` specifying one of the prototypes given in section [4.22.3](#). The incoming and the outgoing type of the function must be equal to the source and target type of the mapping, respectively. The function may be written in TTCN-3, C++ or generated automatically by the compiler. This mapping does not have any options.  
Keyword used in attribute `user` of port type definition: `function`.

Prepared (Subject resp) ETHBAAT Jenő Balasko		No. 2/198 17-CRL 113 200/5 Uen		
Approved (Document resp) ETHLEL Elemer Lelik	Checked ETHGRY	Date 2015-05-15	Rev C	Reference

#### 4.22.2.2 Mapping with One Target

Generally speaking, a source type may have one or more targets. Every mapping target can be used alone. However, only one target can be designated with the following rules if

- no conversion takes place (keyword `simple`);
- encoding a structured message (keyword `encode`)<sup>15</sup>;
- an (external) function with prototype `convert` or `fast` is invoked

#### 4.22.2.3 Mapping with More Targets

On the other hand, more than one target is needed, when the type of an encoded message must be reconstructed. An octetstring, for example, can be decoded to a value of more than one structured PDU type. It is not necessary to specify mutually exclusive decoder rules. It is possible and useful to define a catch-all rule at the end to handle invalid messages.

The following rules may be used with more than one target if

- an (external) function with prototype `backtrack` is invoked;
- decoding a structured message (keyword `decode`);
- (as a last alternative) the source message is `discarded`

The conversion rules are tried in the same order as given in the attribute until one of them succeeds, that is, the function returns `0 OK` or decoding is completed without any error. The outcome of the successful conversion will be the mapped result of the source message. If all conversion rules fail and the last alternative is `discard`, then the source message is discarded. Otherwise dynamic test case error occurs.

#### 4.22.2.4 Mapping from Sliding Buffer

Using sliding buffers is necessary for example, if a stream-based transport, like TCP, is carrying the messages. A stream-based transport is destroying message boundaries: a message may be torn apart or subsequent messages may stick together.

The following rules may be used with more than one target when there is a sliding buffer on the source side if

- an (external) function with prototype `sliding` is invoked;

---

<sup>15</sup> Failure to encode a message leads to dynamic test case error.

Prepared (Subject resp) ETHBAAT Jenő Balasko		No. 2/198 17-CRL 113 200/5 Uen		
Approved (Document resp) ETHLEL Elemer Lelik	Checked ETHGRY	Date 2015-05-15	Rev C	Reference

- decoding a structured message (keyword `decode`)

Above rules imply that the source type of this mapping be either `octetstring` or `charstring`. The run-time environment maintains a separate buffer for each connection of the dual-faced port. Whenever data arrives to the buffer, the conversion rules are applied on the buffer in the same order as given in the attribute. If one of the rules succeeds (that is, the function returns 0 or decoding is completed without any error) the outcome of the conversion will appear on the destination side. If the buffer still contains data after successful decoding, the conversion is attempted again to get the next message.

If one of the rules indicates that the data in the buffer is insufficient to get an entire message (the function returns 2 `INCOMPLETE_MESSAGE` or decoding fails with error code `ET_INCOMPL_MSG`), then the decoding is interrupted until the next fragment arrives in the buffer. If all conversion rules fail (the function returns 1 `NOT_MY_TYPE` or decoding fails with any other error code than `ET_INCOMPL_MSG`), dynamic test case error occurs.

#### 4.22.3 Encoder/decoder Function Prototypes

Encoder/decoder functions are used to convert between different data (message) structures. We can consider e.g. an octet string received from the remote system that should be passed to the upper layer as a TCP message.

Prototypes are attributes governing data input/output rules and conversion result indication. In other words, prototypes are setting the data interface types. The compiler will verify that the parameters and return value correspond to the given prototype. Any TTCN-3 function (even external ones) may be defined with a prototype. There are four prototypes defined as follows:

- prototype `convert`

Functions of this prototype have one parameter (i.e. the data to be converted), which shall be an `in` value parameter, and the result is obtained in the return value of the function.

Example:

```
external function f_convert(in A param_ex) return B
  with { extension "prototype(convert)" }
```

The input data received in the parameter `param_ex` of type A is converted. The result returned is of type B.

- prototype `fast`

Functions of this prototype have one input parameter (the same as above) but the result is obtained in an `out` value parameter rather than in return value. Hence, a faster operation is possible as there is no need to copy the result if the target variable is passed to the function. The order of the parameters is

Prepared (Subject resp) ETHBAAT Jenő Balasko		No. 2/198 17-CRL 113 200/5 Uen		
Approved (Document resp) ETHLEL Elemer Lelik	Checked ETHGRY	Date 2015-05-15	Rev C	Reference

fixed: the first one is always the input parameter and the last one is the output parameter.

Example:

```
external function f_fast(in A param_1, out B param_2)
  with { extension "prototype(fast)" }
```

The input data received in the parameter `param_1` of type A is converted. The resulting data of type B is contained in the output parameter `param_2` of type B.

- `prototype backtrack`

Functions of this prototype have the same data input/output structure as of prototype `fast`, but there is an additional integer value returned to indicate success or failure of the conversion process. In case of conversion failure the contents of the output parameter is undefined. These functions can only be used for decoding. The following return values are defined to indicate the outcome of the decoding operation:

0 (OK). Decoding was successful; the result is stored in the out parameter.

1 (NOT\_MY\_TYPE). Decoding was unsuccessful because the input parameter does not contain a valid message of type B. The content of the out parameter is undefined.

Example:

```
external function f_backtrack(in A param_1, out B param_2) return integer
  with { extension "prototype(backtrack)" }
```

The input data received in the parameter `param_1` of type A is converted. The resulting data of type B is contained in the output parameter `param_2` of type B. The function return value (an integer) indicates success or failure of the conversion process.

- `prototype sliding`

Functions of this prototype have the same behavior as the one of prototype `backtrack`, consequently, these functions can only be used for decoding. The difference is that there is no need for the input parameter to contain exactly one message: it may contain a fragment of a message or several concatenated messages stored in a FIFO buffer. The first parameter of the function is an `inout` value parameter, which is a reference to a buffer of type `octetstring` or `charstring`. The function attempts to recognize an entire message. If it succeeds, the message is removed from the beginning of the FIFO buffer, hence the name of this prototype: sliding (buffer). In case of failure the contents of the buffer remains unchanged. The return value indicates success or failure of the conversion process or insufficiency of input data as follows:

Prepared (Subject resp) ETHBAAT Jenő Balasko		No. 2/198 17-CRL 113 200/5 Uen		
Approved (Document resp) ETHLEL Elemer Lelik	Checked ETHGRY	Date 2015-05-15	Rev C	Reference

0 (OK). Decoding was successful; the result is stored in the out parameter. The decoded message was removed from the beginning of the inout parameter which is used as a sliding buffer.

1 (NOT\_MY\_TYPE). Decoding was unsuccessful because the input parameter does not contain or start with a valid message of type B. The buffer (inout parameter) remains unchanged. The content of out parameter is undefined.

2 (INCOMPLETE\_MESSAGE). Decoding was unsuccessful because the input stream does not contain a complete message (i.e. the end of the message is missing). The input buffer (inout parameter) remains unchanged. The content of out parameter is undefined.

Example:

```
external function f_sliding(inout A param_1, out B param_2) return integer
    with { extension "prototype(sliding)" }
```

The first portion of the input data received in the parameter `param_1` of type A is converted. The resulting data of type B is contained in the output parameter `param_2` of type B. The return value indicates the outcome of the conversion process.

#### 4.22.4 Automatic Generation of Encoder/decoder Functions

Encoding and decoding is performed by C++ external functions using the built-in codecs. These functions can be generated automatically by the compiler. The present section deals with attributes governing the function generation.

##### 4.22.4.1 Input and Output Types

Automatically generated encoder/decoder functions must have an attribute `prototype` assigned. If the encoder/decoder function has been written manually, only the attribute `prototype` may be given. Automatically generated encoder/decoder functions must have either the attribute `encode` or the attribute `decode`. In the case of encoding, the input type of the function must be the (structured) type to be encoded, which in turn must have the appropriate encoding attributes needed for the specified encoding method. The output type of the encoding procedure must be `octetstring` (BER, RAW, XER and JSON coding) or `charstring` (TEXT coding). In case of decoding the functions work the other way around: the input type is `octetstring` or `charstring` and the output type can be any (structured) type with appropriate encoding attributes.

##### 4.22.4.2 Attribute Syntax

The syntax of the `encode` and `decode` attributes is the following:

Prepared (Subject resp) ETHBAAT Jenő Balasko		No. 2/198 17-CRL 113 200/5 Uen		
Approved (Document resp) ETHLEL Elemer Lelik	Checked ETHGRY	Date 2015-05-15	Rev C	Reference

```
("encode"|"decode") " ("("RAW"|"BER"|"TEXT"|"XER"|"JSON") [":" <codec_options>]
")"
```

BER encoding can be applied only for ASN.1 types.

The `<codec_options>` part specifies extra options for the particular codec. Currently it is applicable only in case of BER and XML encoding/decoding. The `codec_options` are copied transparently to the parameter list of the C++ encoder/decoder function call in the generated function body without checking the existence or correctness of the referenced symbols.

Example of prototype `convert`, BER encoding and decoding (the PDU is an ASN.1 type):

```
external function encode_PDU(in PDU pdu) return octetstring
  with { extension "prototype(convert) encode(BER:BER_ENCODE_DER)" }
external function decode_PDU(in octetstring os) return PDU
  with { extension "prototype(convert) decode(BER:BER_ACCEPT_ALL)" }
```

Example of prototype `convert`, XML encoding and decoding (the PDU is a TTCN-3 type):

```
external function encode_PDU(in PDU pdu) return octetstring
  with { extension "prototype(convert) encode(XER:XER_EXTENDED)" }
external function decode_PDU(in octetstring os) return PDU
  with { extension "prototype(convert) decode(XER:XER_EXTENDED)" }
```

#### 4.22.4.3 Codec Error Handling

The TITAN codec API has some well defined function calls that control the behavior of the codecs in various error situations during encoding and decoding. An error handling method is set for each possible error type. The default error handling method can be overridden by specifying the `errorbehavior` attribute:

```
"errorbehavior" "(" <error_type> ":" <error_handling>
  { ", " <error_type> ":" <error_handling> } ")"
```

Possible error types and error handlings are defined in [\[16\]](#), section "The common API". The value of `<error_type>` shall be a value of type `error_type_t` without the prefix `ET_`. The value of `<error_handling>` shall be a value of type `error_behavior_t` without the prefix `EB_`.

The TTCN-3 attribute `errorbehavior(INCOMPL_ANY:ERROR)`, for example, will be mapped to the following C++ statement:

```
TTCN_EncDec::set_error_behavior(TTCN_EncDec::ET_INCOMPL_ANY,
TTCN_EncDec::EB_ERROR);
```

When using the `backtrack` or `sliding` decoding functions, the default error behavior has to be changed in order to avoid a runtime error if the `in` or `inout` parameter does not contain a type we could decode. With this change an integer value is returned carrying the fault code. Without this change a dynamic test case error is generated. Example:

Prepared (Subject resp) ETHBAAT Jenő Balasko		No. 2/198 17-CRL 113 200/5 Uen		
Approved (Document resp) ETHLEL Elemer Lelik	Checked ETHGRY	Date 2015-05-15	Rev C	Reference

```
external function decode_PDU(in octetstring os, out PDU pdu) return integer
with {
    extension "prototype(backtrack)"
    extension "decode(BER:BER_ACCEPT_LONG|BER_ACCEPT_INDEFINITE)"
    extension "errorbehavior(ALL:WARNING)"
}
```

#### 4.22.5 Common Syntax of Attributes

All information related to implicit message encoding shall be given as `extension` attributes of the relevant TTCN–3 definitions. The attributes have a common basic syntax, which is applicable to all attributes given in this section:

- Whitespace characters (spaces, tabulators, newlines, etc.) and TTCN–3 comments are allowed anywhere in the attribute text. Attributes containing only comments, whitespace or both are simply ignored  
Example:

```
with { extension "/* this is a comment */" }
```

- When a definition has multiple attributes, the attributes can be given either in one attribute text separated by whitespace or in separate TTCN–3 attributes.

Example:

```
with { extension "address provider" } means exactly the
same as
with { extension "address"; extension "provider" }
```

- Settings for a single attribute, however, cannot be split in several TTCN–3 attributes.

Example of an invalid attribute:

```
with { extension "prototype(; extension "convert)" }
```

- Each kind of attribute can be given at most once for a definition.

Example of an invalid attribute:

```
with { extension "internal internal" }
```

- The order of attributes is not relevant.

Example: `with { extension "prototype(fast) encode(RAW)" }` means exactly the same as

```
with { extension "encode(RAW) prototype(fast)" }
```

- The keywords introduced in this section, which are not TTCN–3 keywords, are not reserved words. The compiler will recognize the word properly if it has a different meaning (e.g. the name of a type) in the given context.

Example: the attribute

```
with { extension "user provider in(internal -
> simple: function(prototype))" } can be a valid if there is a
port type named provider; internal and simple are message
types and prototype is the name of a function.
```

#### 4.22.6 API describing External Interfaces

Since the default class hierarchy of test ports does not allow sharing of C++ code with other port types, an alternate internal API is introduced for port types describing external interfaces. This alternate internal API is selected by giving the appropriate TTCN-3 extension attribute to the port. The following extension attributes or attribute combinations can be used:

**Table 6 Port extension attributes**

Attribute(s)	Test Port	Communication with SUT allowed	Using of SUT addresses allowed	External interface	Notes
nothing	normal	yes	no	own	
internal	none	no	no	own	
address	see <a href="#">[16]</a> "Support of address type"	yes	yes	own	
provider	see <a href="#">[16]</a> "Provider port types"	yes	no	own	
internal provider	none	no	no	own	means the same as internal
address provider	see <a href="#">[16]</a> "Support of address type" and "Provider port types"	yes	yes	own	
user PT ...	none	yes	depends on PT	PT	PT must have attribute provider
internal user PT ...	none	no	no	PT	PT can have any attributes

Prepared (Subject resp) ETHBAAT Jeno Balasko		No. 2/198 17-CRL 113 200/5 Uen		
Approved (Document resp) ETHLEL Elemer Lelik	Checked ETHGRY	Date 2015-05-15	Rev C	Reference

Attribute(s)	Test Port	Communication with SUT allowed	Using of SUT addresses allowed	External interface	Notes
address user PT ...	none	yes	yes	PT	PT must have attributes address and provider

Prepared (Subject resp) ETHBAAT Jeno Balasko		No. 2/198 17-CRL 113 200/5 Uen

### Example

```
type record ControlRequest { }
type record ControlResponse { }
type record PDUType1 { }
type record PDUType2 { }
// the encoder/decoder functions are written in C++
external function enc_PDUType1(in PDUType1 par) return octetstring
  with { extension "prototype(convert)" }
external function dec_PDUType1(in octetstring stream,
                              out PDUType1 result) return integer
  with { extension "prototype(backtrack)" }

// port type PT1 is the external interface of the dual-faced port
// with its own Test Port. See section "The purpose of Test Ports" in the API
guide.
type port PT1 message {
  out ControlRequest;
  in ControlResponse;
  inout octetstring;
} with { extension "provider" }

// port type PT2 is the internal interface of the dual-faced port
// This port is communicating directly with the SUT using the Test Port of PT1.
type port PT2 message {
  out ControlRequest;
  inout PDUType1, PDUType2;
} with { extension "user PT1
  out(ControlRequest -> ControlRequest: simple;
    PDUType1 -> octetstring: function(enc_PDUType1);
    PDUType2 -> octetstring: encode(RAW))
  in(ControlResponse -> - : discard;
    octetstring -> PDUType1: function(dec_PDUType1),
    PDUType2: decode(RAW),
    - : discard)"
}

type component MTC_CT {
  port PT2 MTC_PORT;
}

type component SYSTEM_SCT {
  port PT1 SYSTEM_PORT;
}

testcase tc_DUALFACED () runs on MTC_CT system SYSTEM_SCT
{
  map(mtc:MTC_PORT, system:SYSTEM_PORT);

  MTC_PORT.send(PDUType1:{...});
  MTC_PORT.receive(PDUType1:?);
}
```

The external face of the dual-faced port (defined by PT1) sends and receives the protocol messages as octetstrings. On the internal face of the same dual-faced port (defined by PT2) the octetstring is converted to two message types (PDUType1, PDUType2). The conversion happens both when sending and when receiving messages.

When sending messages, messages of type PDUType1 will be converted as defined by the function enc\_PDUType1; whereas messages of type PDUType2 will be converted using the built-in conversion rules RAW.

When a piece of octetstring is received, decoding will first be attempted using the function dec\_PDUType1; in successful case the resulting structured type has PDUType1. When decoding using the function dec\_PDUType1 is

Prepared (Subject resp) ETHBAAT Jenő Balasko		No. 2/198 17-CRL 113 200/5 Uen		
Approved (Document resp) ETHLEL Elemer Lelik	Checked ETHGRY	Date 2015-05-15	Rev C	Reference

unsuccessful, the octetstring is decoded using the built-in conversion rules RAW; the resulting message is of type `PDUType2`. When none of the above conversion succeeds, the octetstring will be discarded.

`ControlRequest` and `ControlResponse` will not be affected by a conversion in either direction.

Figure 1 Dual-faced port

## 4.23 RAW Encoder and Decoder

The RAW encoder and decoder are general purpose functionalities developed originally for handling legacy protocols.

The encoder converts abstract TTCN-3 structures (or types) into a bitstream suitable for serial transmission.

The decoder, on the contrary, converts the received bitstream into values of abstract TTCN-3 structures.

This section covers the coding rules in general ([4.23.1](#)), the attributes controlling them ([4.23.4](#)) and the attributes allowed for a particular type ([4.23.5](#)).

You can use the encoding rules defined in this section to encode and decode the following TTCN-3 types:

- bitstring
- boolean
- charstring
- enumerated
- float
- hexstring
- integer
- octetstring

Prepared (Subject resp) ETHBAAT Jeno Balasko		No. 2/198 17-CRL 113 200/5 Uen		
Approved (Document resp) ETHLEL Elemer Lelik	Checked ETHGRY	Date 2015-05-15	Rev C	Reference

- record
- record of, set of
- set
- union

The compiler will produce code capable of RAW encoding/decoding if

- 1 The module has attribute 'encode "RAW"', in other words at the end of the module there is a text  
`with { encode "RAW" }`
- 2 Compound types have at least one `variant` attribute.  
When a compound type is only used internally or it is never RAW encoded/decoded then the attribute `variant` has to be omitted.

Note 1: When a type can be RAW encoded/decoded but with default specification then the empty variant specification can be used: `variant ""`.

Note 2: In order to reduce the code size the TITAN compiler only add the RAW encoding if

- a Either the type has a RAW variant attribute OR
- b The type is used by an upper level type definition with RAW variant attribute.

Example: In this minimal introductory example there are two types to be RAW encoded: OCT2 and CX\_Frame but only the one of them has RAW variant attribute.

```
module Frame {  
  
    external function enc_CX_frame( in CX_Frame cx_message ) return octetstring  
        with { extension "prototype(convert) encode(RAW)" }  
  
    external function dec_CX_frame( in octetstring stream ) return CX_Frame  
        with { extension "prototype(convert) decode(RAW)" }  
  
    type octetstring OCT2 length(2);  
  
    type record CX_Frame  
    {  
        OCT2          data_length,  
        octetstring   data_stream  
    } with { variant "" }  
  
} with { encode "RAW" }
```

#### 4.23.1 General Rules and Restrictions

The TTCN-3 standard defines a mechanism using `attributes` to define, among others, encoding variants (see [\[1\]](#), chapter 27 "Specifying attributes"). However, the `attributes` to be defined are implementation specific. This and the following chapters describe each `attribute` available in TITAN.

Prepared (Subject resp) ETHBAAT Jeno Balasko		No. 2/198 17-CRL 113 200/5 Uen		
Approved (Document resp) ETHLEL Elemer Lelik	Checked ETHGRY	Date 2015-05-15	Rev C	Reference

#### 4.23.1.1 General Rules

If an `attribute` can be assigned to a given type, it can also almost always be assigned to the same type of fields in a `record`, `set` or `union`. Attributes belonging to a `record` or `set` field overwrites the effect of the same attributes specified for the type of the field.

The location of an attribute is evaluated before the attribute itself. This means that if an attribute is overwritten thanks to its qualification or the overwriting rules, or both, its validity at the given location will not be checked.

It is not recommended to use the attributes `LENGTHTO`, `LENGTHINDEX`, `TAG`, `CROSSTAG`, `PRESENCE`, `UNIT`, `POINTERTO`, `PTROFFSET` with dotted qualifiers as it may lead to confusion.

Octetstrings and records with extension bit shall be octet aligned. That is, they should start and end in octet boundary.

Error encountered during the encoding or decoding process are handled as defined in section “Setting error behavior” in [\[16\]](#).

#### 4.23.2 Rules Concerning the Encoder

The encoder doesn't modify the data to be encoded; instead, it substitutes the value of calculated fields (`length`, `pointer`, `tag`, `crosstag` and `presence` fields) with the calculated value in the encoded bitfield if necessary.

The value of the `pointer` and `length` fields are calculated during encoding and the resulting value will be used in sending operations. During decoding, the decoder uses the received length and pointer information to determine the length and the place of the fields.

During encoding, the encoder sets the value of the `presence`, `tag` and `crosstag` fields according to the presence of the `optional` and `union` fields.

#### 4.23.3 Rule Concerning the Decoder

The decoder determines the presence of the optional fields on the basis of the value of the `tag`, `crosstag` and `presence` fields.

#### 4.23.4 Attributes

An `attribute` determines coding and encoding rules. In this section the `attributes` are grouped according to their function.

Prepared (Subject resp) ETHBAAT Jeno Balasko		No. 2/198 17-CRL 113 200/5 Uen		
Approved (Document resp) ETHLEL Elemer Lelik	Checked ETHGRY	Date 2015-05-15	Rev C	Reference

#### 4.23.4.1 Attributes Governing Conversion of TTCN-3 Types into Bitfields

This section defines the attributes describing how a TTCN-3 type is converted to a bitfield.

### BITORDERINFIELD

Attribute syntax: `BITORDERINFIELD(<parameter>)`

Parameters allowed:      `msb`  
                             `lsb`

Default value:              `lsb`

Can be used with:          stand-alone types, or a field of a `record` or `set`.

Description: This attribute specifies the order of the bits within a field. When set to `msb`, the first bit sent will be the most significant bit of the original field. When set to `lsb`, the first bit sent will be the least significant bit of the original field.

Comment: The effect of `BITORDERINFIELD(msb)` is equal to the effect of `BITORDER(msb) BYTORDER(last)`.

#### Example:

```
type bitstring BITn
with {
    variant "BITORDERINFIELD(lsb)"
}
const BITn c_bits := '10010110'B

//Encoding of c_bits gives the following result: 10010110

type bitstring BITnreverse
with {
    variant "BITORDERINFIELD(msb)"
}
const BITnreverse c_bitsrev := '10010110'B
//Encoding of c_bitsrev gives the following result: 01101001
```

### COMP

Attribute syntax: `COMP(<parameter>)`

Parameters allowed:      `nosign`  
                             `2scompl`  
                             `signbit`

Default value:              `nosign`

Can be used with:          stand-alone types or the field of a `record` or `set`.

Prepared (Subject resp) ETHBAAT Jeno Balasko		No. 2/198 17-CRL 113 200/5 Uen		
Approved (Document resp) ETHLEL Elemer Lelik	Checked ETHGRY	Date 2015-05-15	Rev C	Reference

**Description:** This attribute specifies the type of encoding of negative integer numbers as follows:  
nosign: negative numbers are not allowed;  
2scompl: 2's complement encoding;  
signbit: sign bit and the absolute value is coded.  
(Only with integer and enumerated types.)

#### Examples:

```
//Example number 1): coding with sign bit
type integer INT1
with {
    variant "COMP(signbit)";
    variant "FIELDLENGTH(8)"
}

const INT1 c_i := -1

//Encoded c_i: 10000001 '81'O
//    sign bit^

//Example number 2): two's complement coding
type integer INT2 with {variant "COMP(2scompl)";
    variant "FIELDLENGTH(8)"
}

const INT2 c_i2 := -1

//Encoded c_i2: 11111111 'FF'O
```

### FIELDLENGTH

**Attribute syntax:** FIELDLENGTH(<parameter>)

**Parameters allowed:** variable  
positive integer

**Default value:** variable  
8 (for integer type only)

**Can be used with:**

- integer;
- enumerated;
- octetstring;
- charstring;
- bitstring;
- hexstring;
- record fields;
- set fields;
- record of types;
- set of types.

**Description:** FIELDLENGTH specifies the length of the encoded type.

The units of the parameter value for specific types are the following:

Prepared (Subject resp) ETHBAAT Jeno Balasko		No. 2/198 17-CRL 113 200/5 Uen		
Approved (Document resp) ETHLEL Elemer Lelik	Checked ETHGRY	Date 2015-05-15	Rev C	Reference

```
integer, enumerated, bitstring:    bits;
octetstring:                      octets;
hexstring:                        hex    digits;
set of/record of:                 elements.
```

The value 0 means variable length or, in case of the enumerated type, the minimum number of bits required to display the maximum enumerated value.

Integer cannot be coded with variable length.

**Comment:** If FIELDLENGTH is not specified, but a TTCN-3 length restriction with a fixed length is, then the restricted length will be used as FIELDLENGTH.

### Examples:

```
//Example number 1): variable length octetstring
type octetstring OCTn
with {
    variant "FIELDLENGTH(variable)"
}

//Example number 2): 22 bit length bitstrings
type bitstring BIT22
with {
    variant "FIELDLENGTH(22)"
}
type record SomeRecord {
    bitstring field
}
with {
    variant (field) "FIELDLENGTH(22)"
}
```

## FORMAT

**Attribute syntax:** FORMAT (<parameter>)

**Parameters allowed:** IEEE754 double  
IEEE754 float

**Default value:** IEEE754 double

**Can be used with:** float type.

**Description:** FORMAT specifies the encoding format of float values.  
IEEE754 double: The float value is encoded as specified in standard IEEE754 using 1 sign bit, 11 exponent bits and 52 bits for mantissa.  
IEEE754 float: The float value is encoded as specified in standard IEEE754 using 1 sign bit, 8 exponent bits and 23 bits for mantissa.

Prepared (Subject resp) ETHBAAT Jeno Balasko		No. 2/198 17-CRL 113 200/5 Uen		
Approved (Document resp) ETHLEL Elemer Lelik	Checked ETHGRY	Date 2015-05-15	Rev C	Reference

#### Examples:

```
//Example number 1): single precision float
type float Single_float
with {
    variant "FORMAT(IEEE754 float)"
}

//Example number 2): double precision float
type float Double_float
with {
    variant "FORMAT(IEEE754 double)"
}
```

#### 4.23.4.2 Attributes Controlling Conversion of Bitfields into a Bitstream

This section defines the attributes describing how bits and octets are put into the buffer.

#### BITORDER

Attribute syntax: `BITORDER(<parameter>)`

Parameters allowed:      `msb`  
                               `lsb`

Default value:              `lsb`

Can be used with:          stand-alone types or the field of a `record` or `set`.

Description: This attribute specifies the order of the bits within an octet. When set to `lsb`, the first bit sent will be the least significant bit of the original byte. When set to `msb`, the first bit sent will be the most significant bit of the original byte. When applied to an `octetstring` using the extension bit mechanism, only the least significant 7 bits are reversed, the 8<sup>th</sup> bit is reserved for the extension bit.

Examples:

Prepared (Subject resp) ETHBAAT Jeno Balasko		No. 2/198 17-CRL 113 200/5 Uen		
Approved (Document resp) ETHLEL Elemer Lelik	Checked ETHGRY	Date 2015-05-15	Rev C	Reference

```
// Example number 1)
type octetstring OCT
with {
    variant "BITORDER(lsb)"
}

const OCT c_oct := '123456'O

//The encoded bitfield: 01010110 00110100 00010010
//                        last octet^          ^first octet

// The buffer will have the following content:
//      00010010
//      00110100
//      01010110

//The encoding result in the octetstring '123456'O
//Example number 2)
type octetstring OCTrev
with {
    variant "BITORDER(msb)"
}
const OCTrev c_octr := '123456'O
//The encoded bitfield: 01010110 00110100 00010010
//                        last octet^          ^first octet
//The buffer will have the following content:
// 01001000
// 00101100
// 01101010

//The encoding results in the octetstring '482C6A'O

//Example number 3)
type bitstring BIT12 with {
    variant "BITORDER(lsb), FIELDLENGTH(12)"
}
const BIT12 c_bits:='101101101010'B
//The encoded bitfield: 1011 01101010
//                        last octet^          ^first octet

The buffer will have the following content:
// 01101010
// ....1011
//      ^ next field
//The encoding will result in the octetstring '6A.9'O

//Example number 4)
type bitstring BIT12rev with {
    variant "BITORDER(msb), FIELDLENGTH(12)"
}

const BIT12 c_BIT12rev:='101101101010'B

//The encoded bitfield: 1011 01101010
//                        last octet^          ^first octet

//The buffer will have the following content:
// 01010110
// ....1101
//      ^ next field
//The encoding will result in the octetstring '56.D'O
```

## BYTEORDER

Attribute syntax: `BYTEORDER(<parameter>)`

Prepared (Subject resp) ETHBAAT Jeno Balasko		No. 2/198 17-CRL 113 200/5 Uen		
Approved (Document resp) ETHLEL Elemer Lelik	Checked ETHGRY	Date 2015-05-15	Rev C	Reference

Parameters allowed:     `first`  
                              `last`

Default value:            `first`

Can be used with:         stand-alone types or the field of a `record` or `set`.

Description:     The attribute determines the order of the bytes in the encoded data.

`first`: The first octet placed first into the buffer.

`last`: The last octet placed first into the buffer.

Comment:         The attribute has no effect on a single octet field.

Note:             The attribute works differently for `octetstring` and `integer` types.

                  The ordering of bytes is counted from left-to-right (starting from the MSB) in an `octetstring` but right-to-left (starting from the LSB) in an `integer`. Thus, the attribute `BYTEORDER(first)` for an `octetstring` results the same encoded value than `BYTEORDER(last)` for an `integer` having the same value.

Examples:

Prepared (Subject resp) ETHBAAT Jeno Balasko		No. 2/198 17-CRL 113 200/5 Uen		
Approved (Document resp) ETHLEL Elemer Lelik	Checked ETHGRY	Date 2015-05-15	Rev C	Reference

```
//Example number 1)
type octetstring OCT
with {
    variant "BYTEORDER(first)"
}
const OCT c_oct := '123456'O
//The encoded bitfield: 01010110 00110100 00010010
//      last octet^          ^first octet
The buffer will have the following content:
// 00010010
// 00110100
// 01010110
//The encoding will result in the octetstring '123456'O

//Example number 2)
type octetstring OCTrev
with {variant "BYTEORDER(last)"
}

const OCTrev c_octr := '123456'O

//The encoded bitfield: 01010110 00110100 00010010
//      last octet^          ^first octet

//The buffer will have the following content:
//      01010110
// 00110100
// 00010010

The encoding will result in the octetstring '563412'O

//Example number 3)
type bitstring BIT12 with {
    variant "BYTEORDER(first), FIELDLENGTH(12)"
}
const BIT12 c_bits:='100101101010'B
//The encoded bitfield: 1001 01101010
//      last octet^          ^first octet
The buffer will have the following content:
// 01101010
// ....1001
//      ^ next field
//The encoding will result in the octetstring '6A.9'O
//Example number 4)
type bitstring BIT12rev with {
    variant "BYTEORDER(last), FIELDLENGTH(12)"
}

const BIT12rev c_bits:='100101101010'B

//The encoded bitfield: 1001 01101010
//      last octet^          ^first octet

//The buffer will have the following content:
// 10010110
// ....1010
//      ^ next field
//The encoding will result in the octetstring '96.A'O
```

## FIELDORDER

Attribute syntax: FIELDORDER(<parameter>)

Parameters allowed:     msb  
                           lsb

Default value: lsb

Prepared (Subject resp) ETHBAAT Jeno Balasko		No. 2/198 17-CRL 113 200/5 Uen		
Approved (Document resp) ETHLEL Elemer Lelik	Checked ETHGRY	Date 2015-05-15	Rev C	Reference

Can be used with: `record` or `set` types. It can also be assigned to a group of fields of a `record`.

Description: The attribute specifies the order in which consecutive fields of a structured type are placed into octets.

`msb`: coded bitfields are concatenated within an octet starting from MSB, when a field stretches the octet boundary, it continues at the MSB of next the octet.

`lsb`: coded bitfields are concatenated within an octet starting from LSB, when a field stretches the octet boundary, it continues at the LSB of next the octet.

Comment: Fields within an octet must be coded with the same `FIELDORDER`.  
Fields are always concatenated in increasing octet number direction.  
`FIELDORDER` has a slightly different effect than order attributes. While the `FIELDORDER` shifts the location of coded bitfields inside octets, the order attributes describes the order of the bits within a bitfield. There is NO connection between the effect of the `FIELDORDER` and the effects of the other order attributes.

Examples:

Prepared (Subject resp) <b>ETHBAAT</b> Jeno Balasko		No. 2/198 17-CRL 113 200/5 Uen		
Approved (Document resp) <b>ETHLEL</b> Elemer Lelik	Checked <b>ETHGRY</b>	Date 2015-05-15	Rev C	Reference

```
//Example number 1)
type record MyRec_lsb {
    BIT1 field1,
    BIT2 field2,
    BIT3 field3,
    BIT4 field4,
    BIT6 field5
}
with { variant "FIELDORDER(lsb)" }

const MyRec_lsb c_pdu := {
    field1:='1'B // bits of field1: a
    field2:='00'B // bits of field2: b
    field3:='111'B // bits of field3: c
    field4:='0000'B // bits of field4: d
    field5:='111111'B // bits of field5: e
}
//Encoding of c_pdu will result in:
// 00111001 ddccbbba
// 11111100 eeeeeedd

//Example number 2)
type record MyRec_msb {
    BIT1 field1,
    BIT2 field2,
    BIT3 field3,
    BIT4 field4,
    BIT6 field5
}
with { variant "FIELDORDER(msb)" }

const MyRec_msb c_pdu2 := {
    field1:='1'B // bits of field1: a
    field2:='00'B // bits of field2: b
    field3:='111'B // bits of field3: c
    field4:='0000'B // bits of field4: d
    field5:='111111'B // bits of field5: e
}
//Encoding of c_pdu2 will result in:
// 10011100 abbccdd
// 00111111 ddeeeeee
```

**HEXORDER**

Attribute syntax: **HEXORDER(<parameter>)**

Parameters allowed:      low  
                                 high

Default value:            low

Can be used with:        hexstring or octetstring type.

Description:              Order of the hexs in the encoded data.

low: The hex digit in the lower nibble of the octet is put in the lower nibble of the octet in the buffer.

high: The hex digit in the higher nibble of the octet is put in the lower nibble of the octet in the buffer. (The value is swapped)

Prepared (Subject resp) ETHBAAT Jeno Balasko		No. 2/198 17-CRL 113 200/5 Uen		
Approved (Document resp) ETHLEL Elemer Lelik	Checked ETHGRY	Date 2015-05-15	Rev C	Reference

Comment: Only the whole octet is swapped if necessary. For more details see the example.

#### Examples:

```
//Example number 1)
type hexstring HEX_high
with {variant "HEXORDER(high)"}

const HEX_high c_hexs := '12345'H
//The encoded bitfield: 0101 00110100 00010010
//                      last octet^      ^first octet

//The buffer will have the following content:
// 00010010 12
// 00110100 34
// ....0101 .5
//   ^ next field
//The encoding will result in the octetstring '1234.5'O

//Example number 2)
type hexstring HEX_low
with {variant "HEXORDER(low)"}

const HEX_low c_hexl := '12345'H
//The encoded bitfield: 0101 00110100 00010010
//                      last octet^      ^first octet

//The buffer will have the following content:
// 00100001 21
// 01000011 43
// ....0101 .5 ←not twisted!
//   ^ next field
//The encoding will result in the octetstring '2143.5'O

//Example number 3)
type octetstring OCT
with {variant "HEXORDER(high)"}

const OCT c_hocts := '1234'O
//The encoded bitfield: 00110100 00010010
//                      last octet^      ^first octet
//The buffer will have the following content:
// 00100001 21
// 01000011 43
//The encoding will result in the octetstring '2143'O
```

#### 4.23.4.3 Extension Bit Setting Attributes

This section defines the attributes describing the extension bit mechanism.

The extension bit mechanism allows the size of an Information Element (IE) to be increased by using the most significant bit (MSB, bit 7) of an octet as an extension bit. When an octet within an IE has bit 7 defined as an extension bit, then the value '0' in that bit position indicates that the following octet is an extension of the current octet. When the value is '1', the octet is not continued.

#### EXTENSION\_BIT

Attribute syntax: `EXTENSION_BIT(<parameter>)`

Prepared (Subject resp) ETHBAAT Jeno Balasko		No. 2/198 17-CRL 113 200/5 Uen		
Approved (Document resp) ETHLEL Elemer Lelik	Checked ETHGRY	Date 2015-05-15	Rev C	Reference

Parameters allowed:   no  
                              yes  
                              reverse

Default value: none

Can be used with:

- octetstring,
- (fields of a) record,
- set,
- record of,
- set of.

Description: When `EXTENSION_BIT` is set to `yes`, then each MSB is set to 0 except the last one which is set to 1. When `EXTENSION_BIT` is set to `reverse`, then each MSB is set to 1 and the MSB of the last octet is set to 0 to indicate the end of the Information Element. When `EXTENSION_BIT` is set to `no`, then no changes are made to the MSBs.

Comment: In case of the types `record of` and `set of` the last bit of the element of the structured type will be used as `EXTENSION_BIT`.  
Note, that the data in the MSBs will be overwritten during the encoding. When `EXTENSION_BIT` belongs to a record, the field containing the `EXTENSION_BIT` must explicitly be declared in the type definition. Also the last bit of the element of `record of` and `set of` type shall be reserved for `EXTENSION_BIT` in the type definition.

Examples:

Prepared (Subject resp) <b>ETHBAAT Jeno Balasko</b>		No. <b>2/198 17-CRL 113 200/5 Uen</b>		
Approved (Document resp) <b>ETHLEL Elemer Lelik</b>	Checked <b>ETHGRY</b>	Date <b>2015-05-15</b>	Rev <b>C</b>	Reference

```
//Example number 1)
octetstring OCTn
with {variant "EXTENSION_BIT(reverse)"}

const OCTn c_octs:=‘586211’O

//The encoding will have the following result:
// 11011000
// 11100010
// 00010001
// ^ the overwritten EXTENSION_BITS
//The encoding will result in the octetstring ‘D8E211’O

//Example number 2)
type record Rec3 {
    BIT7 field1,
    BIT1 extbit1,
    BIT7 field2 optional,
    BIT1 extbit2 optional
}
with { variant "EXTENSION_BIT(yes)" }

const Rec3 c_MyRec{
    field1:=‘1000001’B,
    extbit1:=‘1’B,
    field2:=‘1011101’B,
    extbit2:=‘0’B
}

//The encoding will have the following result:
// 01000001
// 11011101
// ^ the overwritten EXTENSION_BITS
The encoding will result in the octetstring ‘41DD’O

//Example number 3)
type record Rec4{
    BIT11 field1,
    BIT1 extbit
}

type record of Rec4 RecList
with { variant "EXTENSION_BIT(yes)"}

const RecList c_recs{
    { field1:=‘10010011011’B, extbit:=‘1’B}
    { field1:=‘11010111010’B, extbit:=‘0’B}
}

//The encoding will have the following result:
// 10011011
// 10100100
// 11101011
// ^ the overwritten EXTENSION_BITS
//The encoding will result in the octetstring ‘9BA4EB’O
```

## EXTENSION\_BIT\_GROUP

Attribute syntax: EXTENSION\_BIT\_GROUP(<param1, param2, param3>)

Parameters allowed: param1:  
no  
yes

Prepared (Subject resp) ETHBAAT Jeno Balasko		No. 2/198 17-CRL 113 200/5 Uen		
Approved (Document resp) ETHLEL Elemer Lelik	Checked ETHGRY	Date 2015-05-15	Rev C	Reference

```
reverse
param2:    first_field_name,
param3: last_field_name
```

Default value: none

Can be used with: a group of `record` fields

Description: The `EXTENSION_BIT_GROUP` limits the extension bit mechanism to a group of the fields of a `record` instead of the whole `record`.  
`first_field_name`: the name of the first field in the group  
`last_field_name`: the name of the last field in the group

Comment: Multiple group definition is allowed to define more groups within one `record`. Every group must be octet aligned and the groups must not overlap.

#### Example:

```
type record MyPDU{
    OCT1 header,
    BIT7 octet2info,
    BIT1 extbit1,
    BIT7 octet2ainfo optional,
    BIT1 extbit2 optional,
    OCT1 octet3,
    BIT7 octet4info,
    BIT1 extbit3,
    BIT7 octet4ainfo optional,
    BIT1 extbit4 optional,
} with {
    variant "EXTENSION_BIT_GROUP(yes,octet2info,extbit2)";
    variant "EXTENSION_BIT_GROUP(yes,octet4info,extbit4)"
}
const MyPDU c_pdu:={
    header:=0F'O,
    octet2info:=1011011'B,
    extbit1:=0'B,
    octet2ainfo:=omit,
    extbit2:=omit,
    octet3:=00'O,
    octet4info:=0110001'B,
    extbit3:=1'B,
    octet4ainfo:=0011100'B,
    extbit4:=0'B,
}

//The encoding will have the following result:
// 00001111
// 11011011
// 00000000
// 00110001
// 10011100
// ^ the overwritten extension bits
//The encoding will result in the octetstring: '0FDB00319C'O
```

#### 4.23.4.4 Attributes Controlling Padding

This section defines the attributes that describe the padding of fields.

Prepared (Subject resp) ETHBAAT Jeno Balasko		No. 2/198 17-CRL 113 200/5 Uen		
Approved (Document resp) ETHLEL Elemer Lelik	Checked ETHGRY	Date 2015-05-15	Rev C	Reference

## ALIGN

Attribute syntax: `ALIGN(<parameter>)`

Parameters allowed:     `left`  
                               `right`

Default value:             `right`

Can be used with:         stand-alone types or the field of a `record` or `set`.

Description:     This attribute has meaning when the length of the actual value can be determined and is less than the specified `FIELDLENGTH`. In such cases the remaining bits/bytes will be padded with zeros. The attribute `ALIGN` specifies the sequence of the actual value and the padding within the encoded bitfield.  
                   `right`: The LSB of the actual value is aligned to the LSB of coded bitfield  
                   `left`: The MSB of the actual value is aligned to the MSB of coded bitfield

Comment:         It has no meaning during decoding except if the length of the actual value can be determined from the length restriction of the type. In this case the `ALIGN` also specifies the order of the actual value and the padding within the encoded bitfield.

### Examples:

```
//Example number 1)
type octetstring OCT10
with {
    variant "ALIGN(left)";
    variant "FIELDLENGTH(10)"
}

const OCT10 c_oct := '0102030405'O

//Encoded value: '01020304050000000000'O
//The decoded value: '01020304050000000000'O

//Example number 2)
type octetstring OCT10length5 length(5)
with {
    variant "ALIGN(left)";
    variant "FIELDLENGTH(10)"
}

const OCT10length5 c_oct5 := '0102030405'O
//Encoded value: '01020304050000000000'O
//The decoded value: '0102030405'O
```

## PADDING

Attribute syntax: `PADDING(<parameter>)`

Prepared (Subject resp) ETHBAAT Jeno Balasko		No. 2/198 17-CRL 113 200/5 Uen		
Approved (Document resp) ETHLEL Elemer Lelik	Checked ETHGRY	Date 2015-05-15	Rev C	Reference

## Parameters allowed:

- no
- yes
- octet
- nibble
- word16
- dword32
- integer to specify the padding unit and allow padding.

Default value: none

Can be used with: This attribute can belong to any types.

Description: This attribute specifies that an encoded type shall **end** at a boundary fixed by a multiple of padding unit bits counted from the beginning of the message.

The default padding unit is 8 bits. If `PADDING` is set to `yes`, then unused bits of the last octets of the encoded type will be filled with padding pattern. If `PADDING` is set to `no`, the next field will use the remaining bits of the last octet. If padding unit is specified, then the unused bits between the end of the field and the next padding position will be filled with padding pattern.

Comment: It is possible to use different padding for every field of structured types. The padding unit defined by `PADDING` and `PREPADDING` attributes can be different for the same type.

Examples:

Prepared (Subject resp) ETHBAAT Jeno Balasko		No. 2/198 17-CRL 113 200/5 Uen		
Approved (Document resp) ETHLEL Elemer Lelik	Checked ETHGRY	Date 2015-05-15	Rev C	Reference

```
//Example number 1)
type BIT5 Bit5padded with { variant "PADDING(yes)"}

const Bit5padded c_bits:='10011'B

//The encoding will have the following result:
// 00010011
// ^ the padding bits
//The encoding will result in the octetstring '13'O

//Example number 2)
type record Paddedrec{
    BIT3 field1,
    BIT7 field2
} with { variant "PADDING(yes)"}

const Paddedrec c_myrec:={
    field1:='101'B,
    field2:='0110100'B
}

//The encoding will have the following result:
// 10100101
// 00000001
// ^ the padding bits
//The encoding will result in the octetstring 'A501'O

//Example number 3): padding to 32 bits
type BIT5 Bit5padded_dw with { variant "PADDING(dword32)"}

const Bit5padded_dw c_dword:='10011'B

//The encoding will have the following result:
// 00010011
// 00000000
// 00000000
// 00000000
// ^ the padding bits
//The encoding will result in the octetstring '13000000'O

//Example number 4)
type record Paddedrec_dw{
    BIT3 field1,
    BIT7 field2
} with { variant "PADDING(dword32)"}

const Paddedrec_dw c_dwords:={
    field1:='101'B,
    field2:='0110100'B
}

//The encoding will have the following result:
// 10100101
// 00000001
// 00000000
// 00000000
// ^ the padding bits
//The encoding will result in the octetstring 'A5010000'O
```

## PADDING\_PATTERN

Attribute syntax: PADDING\_PATTERN(<parameter>)

Parameters allowed: bitstring

Default value: '0'B

Prepared (Subject resp) ETHBAAT Jeno Balasko		No. 2/198 17-CRL 113 200/5 Uen		
Approved (Document resp) ETHLEL Elemer Lelik	Checked ETHGRY	Date 2015-05-15	Rev C	Reference

Can be used with: any type with attributes PADDING or PREPADDING.

Description: This attribute specifies padding pattern used by padding mechanism. The default padding pattern is '0'B. If the specified padding pattern is shorter than the padding space, then the padding pattern is repeated.

Comment: For a particular field or type only one padding pattern can be specified for PADDING and PREPADDING.

#### Examples:

```
//Example number 1)
type BIT8 Bit8padded with {
    variant "PREPADDING(yes), PADDING_PATTERN('1'B)"
}

type record PDU {
    BIT3      field1,
    Bit8padded field2
} with {variant ""}

const PDU c_myPDU:={
    field1:='101'B,
    field2:='10010011'B
}

//The encoding will have the following result:
// 11111101
// 10010011
//the padding bits are indicated in bold

//The encoding will result in the octetstring 'FD93'O

//Example number 2): padding to 32 bits
type BIT8 Bit8pdd with {
    variant "PREPADDING(dword32), PADDING_PATTERN('10'B)"
}

type record PDU{
    BIT3      field1,
    Bit8pdd   field2
} with {variant ""}

const PDU c_myPDUplus:={
    field1:='101'B,
    field2:='10010011'B
}

//The encoding will have the following result:
//      01010101
//      01010101
//      01010101
//      01010101
//      10010011
//The padding bits are indicated in bold

//The encoding will result in the octetstring '555555593'O
```

## PADDALL

Attribute syntax: PADDALL(<parameter>)

Prepared (Subject resp) ETHBAAT Jeno Balasko		No. 2/198 17-CRL 113 200/5 Uen		
Approved (Document resp) ETHLEL Elemer Lelik	Checked ETHGRY	Date 2015-05-15	Rev C	Reference

Can be used with: `record or set`.

Description: If `PADDALL` is specified, the padding parameter specified for a `whole record or set` will be valid for every field of the structured type in question.

Comment: If a different padding parameter is specified for any fields it won't be overridden by the padding parameter specified for the record.

Examples:

Prepared (Subject resp) <b>ETHBAAT Jeno Balasko</b>		No. <b>2/198 17-CRL 113 200/5 Uen</b>		
Approved (Document resp) <b>ETHLEL Elemer Lelik</b>	Checked <b>ETHGRY</b>	Date <b>2015-05-15</b>	Rev <b>C</b>	Reference

```

//Example number 1)
type record Paddedrec{
    BIT3 field1,
    BIT7 field2
} with { variant "PADDING(yes)"}

const Paddedrec c_myrec:={
    field1:='101'B,
    field2:='0110100'B
}

//The encoding will have the following result:
// 10100101
// 00000001
// ^ the padding bits

//The encoding will result in the octetstring 'A501'O

//Example number 2)
type record Paddddd{
    BIT3 field1,
    BIT7 field2
} with { variant "PADDING(yes), PADDALL"}

const Paddddd c_myrec:={
    field1:='101'B,
    field2:='0110100'B
}

//The encoding will have the following result:
// 00000101
// 00110100
// ^ the padding bits

//The encoding will result in the octetstring '0534'O

//Example number 3)
type record Padded{
    BIT3 field1,
    BIT5 field2,
    BIT7 field3
} with { variant "PADDING(yes), PADDALL"}
const Padded c_ourrec:={
    field1:='101'B,
    field2:='10011'B,
    field3:='0110100'B
}
//The encoding will have the following result:
// 00000101
// 00010011
// 00110100
// ^ the padding bits

//The encoding will result in the octetstring '051334'O

//Example number 4): field1 shouldn't be padded
type record Paddd{
    BIT3 field1,
    BIT5 field2,
    BIT7 field3
} with { variant "PADDING(yes), PADDALL";
        variant (field1) "PADDING(no)" }

const Paddd c_myrec:={
    field1:='101'B,
    field2:='10011'B,
    field3:='0110100'B
}

```

Prepared (Subject resp) ETHBAAT Jeno Balasko		No. 2/198 17-CRL 113 200/5 Uen		
Approved (Document resp) ETHLEL Elemer Lelik	Checked ETHGRY	Date 2015-05-15	Rev C	Reference

```
//The encoding will have the following result:  
// 10011101 < field1 is not padded!!!  
// 00110100  
// ^ the padding bit  
  
//The encoding will result in the octetstring '9D34'0
```

## PREPADDING

Attribute syntax: PREPADDING(<parameter>)

Parameters allowed:

- no
- yes
- octet
- nibble
- word16
- dword32
- integer to specify the padding unit and allow padding.

Default value: none

Can be used with: any type.

Description: This attribute specifies that an encoded type shall **start** at a boundary fixed by a multiple of padding unit bits counted from the beginning of the message. The default padding unit is 8 bits. If PREPADDING is set to **yes**, then unused bits of the last octets of the previous encoded type will be filled with padding pattern and the actual field starts at octet boundary. If PREPADDING is set to **no**, the remaining bits of the last octet will be used by the field. If padding unit specified, then the unused bits between the end of the last field and the next padding position will be filled with padding pattern and the actual field starts at from this point.

Comment: It is possible to use different padding for every field of structured types. The padding unit defined by PADDING and PREPADDING attributes can be different for the same type.

Examples:

Prepared (Subject resp) ETHBAAT Jeno Balasko		No. 2/198 17-CRL 113 200/5 Uen		
Approved (Document resp) ETHLEL Elemer Lelik	Checked ETHGRY	Date 2015-05-15	Rev C	Reference

```
//Example number 1)
type BIT8 bit8padded with { variant "PREPADDING(yes)"}

type record PDU{
    BIT3 field1,
    bit8padded field2
} with {variant ""}

const PDU c_myPDU:={
    field1:='101'B,
    field2:='10010011'B
}

//The encoding will have the following result:
// 00000101
//      10010011
//The padding bits are indicated in bold

//The encoding will result in the octetstring '0593'O

//Example number 2): padding to 32 bits
type BIT8 bit8padded_dw with { variant "PREPADDING(dword32)"}

type record PDU{
    BIT3          field1,
    bit8padded_dw field2
} with {variant ""}

const PDU myPDU:={
    field1:='101'B,
    field2:='10010011'B
}

//The encoding will have the following result:
// 00000101
// 00000000
// 00000000
// 00000000
// 10010011
//The padding bits are indicated in bold

//The encoding will result in the octetstring '0500000093'O
```

#### 4.23.4.5 Attributes of Length and Pointer Field

This section describes the coding attributes of fields containing length information or serving as pointer within a `record`.

The length and pointer fields must be of TTCN-3 `integer` type and must have fixed length.

The attributes described in this section are applicable to fields of a `record`.

### LENGHTO

Attribute syntax: `LENGHTO(<parameter>)`

Parameters allowed: list of TTCN-3 field identifiers

Allowed value: any field name

Default value: none

Prepared (Subject resp) ETHBAAT Jeno Balasko		No. 2/198 17-CRL 113 200/5 Uen		
Approved (Document resp) ETHLEL Elemer Lelik	Checked ETHGRY	Date 2015-05-15	Rev C	Reference

Can be used with: fields of a `record`.

Description: The compiler is able to calculate the encoded length of one or several fields and put the result in another field of the same record.

Consider a record with the fields `lengthField`, `field1`, `field2` and `field3`. Here `lengthField` may contain the encoded length of either one field (for example, `field2`), or sum of the lengths of multiple fields ((for example, that of `field2` + `field3`)).

The parameter is the field identifier (or list of field identifiers) of the `record` to be encoded.

Comment: The length is expressed in units defined by the attribute `UNIT` (see section [9](#)). The default unit is `octet`. The length field should be a `TTCN-3 integer` or `union` type.

Special `union` containing only integer fields can be used for variable length field. It must not be used with `LENGTHINDEX`. The length field can be included in to the sum of the lengths of multiple fields (e.g. `lengthField + field2 + field3`).

The `union` field is NOT selected by the encoder. So the suitable field must be selected before encoding!

The fields included in the length computing need not be continuous.

Examples:

Prepared (Subject resp) ETHBAAT Jeno Balasko		No. 2/198 17-CRL 113 200/5 Uen		
Approved (Document resp) ETHLEL Elemer Lelik	Checked ETHGRY	Date 2015-05-15	Rev C	Reference

```
//Example number 1)
type record Rec {
    INT1      length,
    OCT3      field1,
    octetstring field2
}
with {
    variant (length) "LENGTHTO(field1);
    variant (length) "UNIT(bits)"
}

//Example number 2)
type record Rec2 {
    INT1      length,
    OCT3      field1,
    octetstring field2
}
with {
    variant (length) "LENGTHTO(length, field1, field2)
}

//Example number 3)
type record Rec3 {
    INT1      length,
    OCT3      field1,
    OCT1      field2,
    octetstring field3
}
with {
    variant (length) "LENGTHTO(field1, field3)
// field2 is excluded!
}

//Example number 4): using union as length field
type union length_union{
    integer shorc_length_field,
    integer long_length_field
} with {
    variant (shorc_length_field) "FIELDLLENGTH(7)";
    variant (long_length_field) "FIELDLLENGTH(15)";
}
type record Rec4{
    BIT1      flag,
    length_union length_field,
    octetstring data
} with {
    variant (length_field)
        "CROSSTAG(shorc_length_field, flag = '0'B
        long_length_field, flag = '1'B)";
    variant (length_field) "LENGTHTO(data)"
}

//Const for short data. Data is shorter than 127 octets:
const Rec4(octetstring oc):={
    flag      :='0'B,
    length_field:={shorc_length_field:=0},
    data      := oc
}

//Const for long data. Data is longer than 126 octets:
const Rec4(octetstring oc):={
    flag      :='1'B,
    length_field:={long_length_field:=0},
    data      := oc
}
```

## LENGTHINDEX

Prepared (Subject resp) ETHBAAT Jenő Balasko		No. 2/198 17-CRL 113 200/5 Uen		
Approved (Document resp) ETHLEL Elemer Lelik	Checked ETHGRY	Date 2015-05-15	Rev C	Reference

Attribute syntax: `LENGTHINDEX(<parameter>)`

Parameters allowed: `TTCN-3` field identifier

Allowed values: any nested field name

Default value: none

Can be used with: fields of a record.

Description: This attribute extends the `LENGTHTO` attribute with the identification of the nested field containing the length value within the field of the corresponding `LENGTHTO` attribute.

Comment: See also the description of the `LENGTHTO` attribute (section [0](#)). Note that the field named by `LENGTHINDEX` attribute should be a `TTCN-3` integer type.

Example (see also example of `LENGTHTO` attribute).

```
type integer INT1
with {
    variant "FIELDLENGTH(8)"
}

type record InnerRec {
    INT1 length
}
with { variant "" }

type record OuterRec {
    InnerRec    lengthRec,
    octetstring field
}

with {
    variant (lengthRec) "LENGTHTO(field)";
    variant (lengthRec) "LENGTHINDEX(length)"
}
```

## POINTERTO

Attribute syntax: `POINTERTO(<parameter>)`

Parameters allowed: `TTCN-3` field identifier

Default value: none

Can be used with: fields of a record.

Description: Some record fields contain the distance to another encoded field. Records can be encoded in the form of: `ptr1, ptr2, ptr3, field1, field2, field3`, where the position of `fieldN` within the encoded stream can be determined from the value and position of field `ptrN`. The distance of the pointed field from the base field will be `ptrN * UNIT + PTROFFSET`. The default

Prepared (Subject resp) ETHBAAT Jeno Balasko		No. 2/198 17-CRL 113 200/5 Uen		
Approved (Document resp) ETHLEL Elemer Lelik	Checked ETHGRY	Date 2015-05-15	Rev C	Reference

base field is the pointer itself. The base field can be set by the PTROFFSET attribute. When the pointed field is optional, the pointer value 0 indicates the absence of the pointed field.

**Comment:** See also the description of UNIT ([0](#)) and PTROFFSET ([0](#)) attributes. Also note that pointer fields should be TTCN-3 integer type.

#### Examples:

```
type record Rec {
    INT1 ptr1,
    INT1 ptr2,
    INT1 ptr3,
    OCT3 field1,
    OCT3 field2,
    OCT3 field3
}
with {
    variant (ptr1) "POINTERTO(field1)";
    variant (ptr2) "POINTERTO(field2)";
    variant (ptr3) "POINTERTO(field3)"
}

const Rec c_rec := {
    ptr1 := <any value>,
    ptr2 := <any value>,
    ptr3 := <any value>,
    field1 := '010203'O,
    field2 := '040506'O,
    field3 := '070809'O
}

//Encoded c_rec: '030507010203040506070809'O
//The value of ptr1: 03
//PTROFFSET and UNIT are not set, so the default (0) is being //using.
//The starting position of ptr1: 0th bit
//The starting position of field1= 3 * 8 + 0 = 24th bit.
```

## PTROFFSET

**Attribute syntax:** PTROFFSET(<parameter>)

**Parameters allowed:** integer  
TTCN-3 field identifier

**Default value:** 0

**Can be used with:** fields of a record.

**Description:** This attribute specifies where the pointed field area starts and the base field of pointer calculating. The distance of the pointed field from the base field will equal  $\text{ptr\_field} * \text{UNIT} + \text{PTROFFSET}$ .

**Comment:** It can be specified a base field and pointer offset for one field. See also the description of the attributes POINTERTO ([0](#)) and UNIT ([0](#)).

Prepared (Subject resp) ETHBAAT Jeno Balasko		No. 2/198 17-CRL 113 200/5 Uen		
Approved (Document resp) ETHLEL Elemer Lelik	Checked ETHGRY	Date 2015-05-15	Rev C	Reference

### Examples:

```

type record Rec {
    INT2 ptr1,
    INT2 ptr2
    OCT3 field1,
    OCT3 field2
}
with {
    variant (ptr1) "POINTERTO(field1)";
    variant (ptr1) "PTROFFSET(ptr2)";
    variant (ptr2) "POINTERTO(field2)";
    variant (ptr2) "PTROFFSET(field1)"
}
//In the example above the distance will not include
//the pointer itself.

```

## UNIT

Attribute syntax: `UNIT(<parameter>)`

Parameters allowed:

- bits
- octets
- nibble
- word16
- dword32
- elements
- integer

Default value: octets

Can be used with: fields of a record.

Description: `UNIT` attribute is used in conjunction with the `LENGTHTO` ([0](#)) or `POINTERTO` ([0](#)) attributes. Length indicator fields may contain length expressed in indicated number of bits.

Comment: See also description of the `LENGTHTO` and `POINTERTO` attributes. The elements can be used with `LENGTHTO` only if the length field counts the number of elements in a record/set of field.

Examples:

Prepared (Subject resp) ETHBAAT Jeno Balasko		No. 2/198 17-CRL 113 200/5 Uen		
Approved (Document resp) ETHLEL Elemer Lelik	Checked ETHGRY	Date 2015-05-15	Rev C	Reference

```
//Example number 1): measuring length in 32 bit long units
type record Rec {
    INT1      length,
    octetstring field
}
with {
    variant (length) "LENGTHTO(field)";
    variant (length) "UNIT(dword32) "
}

//Example number 2): measuring length in 2 bit long units
type record Rec {
    INT1      length,
    octetstring field
}
with {
    variant (length) "LENGTHTO(field)";
    variant (length) "UNIT(2) "
}

//Example number 3): counting the number of elements of record of field
type record of BIT8 Bitrec

type record Rec{
    integer length,
    Bitrec  data
}
with{
    variant (length) "LENGTHTO(data)";
    variant (length) "UNIT(elements) "
}
```

4.23.4.6      Attributes to Identify Fields in Structured Data Types

This section describes the coding attributes which during decoding identifies the fields within structured data types such as `record`, `set` or `union`.

**PRESENCE**

Attribute syntax:    `PRESENCE(<parameter>)`

Parameters allowed:      a   `presence_indicator`    expression    (see Description)

Default value: none

Can be used with:      optional fields of a record or set.

Description:    Within records some fields may indicate the presence of another optional field. The attribute `PRESENCE` is used to describe these cases. Each optional field can have a `PRESENCE` definition.

The syntax of the `PRESENCE` attribute is the following: a `PRESENCE` definition is a `presence_indicator` expression. `Presence_indicators` are of form `<key> = <constant>` or `{<key1> = <constant1>, <key2> = <constant2>,`

Prepared (Subject resp) ETHBAAT Jeno Balasko		No. 2/198 17-CRL 113 200/5 Uen		
Approved (Document resp) ETHLEL Elemer Lelik	Checked ETHGRY	Date 2015-05-15	Rev C	Reference

... <keyN> = <constantN>} where each key is a field(.nestedField) of the record, set or union and each constant is a TTCN-3 constant expression (for example, 22, '25'O or '1001101'B).

**Comment:** The PRESENCE attribute can identify the presence of the whole record. In that case the field reference must be omitted.

**Examples:**

```
type record Rec {
    BIT1 presence,
    OCT3 field optional
}
with {
    variant (field) "PRESENCE(presence = '1'B)"
}

type record R2{
    OCT1 header,
    OCT1 data
} with {variant "PRESENCE(header='11'O)"}
```

## TAG

**Attribute syntax:** TAG(<parameter>)

**Parameters allowed:** list of field\_identifications (see Description)

**Default value:** none

**Can be used with:** record or set.

**Description:** The purpose of the attribute TAG is to identify specific values in certain fields of the set, record elements or union choices. When the TAG is specified to a record or a set, the presence of the given element can be identified at decoding. When the TAG belongs to a union, the union member can be identified at decoding.

The attribute is a list of field\_identifications. Each field\_identification consists of a record, set or union field name and a presence\_indicator expression separated by a comma (,).

Presence\_indicators are of form <key> = <constant> or { <key1> = <constant1>, <key2> = <constant2>, ... <keyN> = <constantN> } where each key is a field(.nestedField) of the record, set or union and each constant is a TTCN-3 constant expression (e.g. 22, '25'O or '1001101'B).

There is a special presence\_indicator: OTHERWISE. This

Prepared (Subject resp) ETHBAAT Jeno Balasko		No. 2/198 17-CRL 113 200/5 Uen		
Approved (Document resp) ETHLEL Elemer Lelik	Checked ETHGRY	Date 2015-05-15	Rev C	Reference

indicates the default union member in a union when the TAG belongs to union.

**Comment:** TAG works on non-optional fields of a record as well.

It is recommended to use the attributes CROSSTAG or PRESENCE leading to more effective decoding.

### Examples:

```
//Example number 1): set
type record InnerRec {
    INT1 tag,
    OCT3 field
}
with { variant "" }
```

```
type set SomeSet {
    InnerRec field1 optional,
    InnerRec field2 optional,
    InnerRec field3 optional
}
with {
    variant "TAG(field1, tag = 1;
            field2, tag = 2;
            field3, tag = 3)"
}
```

```
//Example number 2): union
type union SomeUnion {
    InnerRec field1,
    InnerRec field2,
    InnerRec field3
}
with {
    variant "TAG(field1, tag = 1;
            field2, tag = 2;
            field3, OTHERWISE)"
}
```

If neither tag=1 in field1 nor tag=2 in field2 are matched, field3 is selected.

```
//Example number 3): record
type record MyRec{
    OCT1 header,
    InnerRec field1 optional
}
with{
    variant (field1) "TAG(field1, tag = 1)"
}
//field1 is present when in field1 tag equals 1.
```

## CROSSTAG

**Attribute syntax:** CROSSTAG(<parameter>)

**Parameters allowed:** list of union field\_identifications (see Description)

**Default value:** none

**Can be used with:** union fields of records.

Prepared (Subject resp) ETHBAAT Jeno Balasko		No. 2/198 17-CRL 113 200/5 Uen		
Approved (Document resp) ETHLEL Elemer Lelik	Checked ETHGRY	Date 2015-05-15	Rev C	Reference

**Description:** When one field of a record specifies the union member of another field of a record, CROSSTAG definition is used.

The syntax of the CROSSTAG attribute is the following. Each union field can have a CROSSTAG definition. A CROSSTAG definition is a list of union field\_identifications.

Each field\_identification consists of a union field name and a presence\_indicator expression separated by a comma (,).

Presence\_indicators are of form <key> = <constant> or {<key1> = <constant1>, <key2> = <constant2>, ... <keyN> = <constantN>} where each key is a field(.nestedField) of the record, set or union and each constant is a TTCN-3 constant expression (for example, 22, '25'O or '1001101'B).

There is a special presence\_indicator: OTHERWISE. This indicates the default union member in union.

**Comment:** The difference between the TAG and CROSSTAG concept is that in case of TAG the field identifier is inside the field to be identified. In case of CROSSTAG the field identifier can either precede or succeed the union field it refers to. If the field identifier succeeds the union, they must be in the same record, the union field must be mandatory and all of its embedded types must have the same fixed size.

#### Examples:

```
type union AnyPdu {
  PduType1 type1,
  PduType2 type2,
  PduType3 type3
}
with { variant "" }

type record PduWithId {
  INT1    protocolId,
  AnyPdu  pdu
}
with {
  variant (pdu) "CROSSTAG( type1, { protocolId = 1,
                                   protocolId = 11 };
                                   type2, protocolId = 2;
                                   type3, protocolId = 3)"
}
```

## REPEATABLE

**Attribute syntax:** REPEATABLE (<parameter>)

**Parameters allowed:** yes, no

Prepared (Subject resp) ETHBAAT Jeno Balasko		No. 2/198 17-CRL 113 200/5 Uen		
Approved (Document resp) ETHLEL Elemer Lelik	Checked ETHGRY	Date 2015-05-15	Rev C	Reference

Default value: none

Can be used with: record/set of type fields of a set.

Description: The element of the set can be in any order. The REPEATABLE attribute controls whether the element of the record or set of can be mixed with other elements of the set or they are grouped together.

Comment: It has no effect during encoding.

#### Examples:

// Three records and a set are defined as follows:

```
type record R1{
    OCT1 header,
    OCT1 data
} with {variant "PRESENCE(header='AA'O)"}

type record of R1 R1list;

type record R2{
    OCT1 header,
    OCT1 data
} with {variant "PRESENCE(header='11'O)"}

type record R3{
    OCT1 header,
    OCT1 data
} with {variant "PRESENCE(header='22'O)"}

type set S1 {
    R2 field1,
    R3 field2,
    R1list field3
}
with {variant (field3) "REPEATABLE(yes)"}
//The following encoded values have equal meaning:
// (The value of R1 is indicated in bold.)
//example1: 1145AA01AA02AA032267
//example2: 1145AA012267AA02AA03
//example3: AA012267AA021145AA03
The decoded value of S1 type:
{
    field1:={
        header:='11'O,
        data:='45'O
    },
    field2:={
        header:='22'O,
        data:='67'O
    },
    field3:={
        {header:='AA'O,data:='01'O},
        {header:='AA'O,data:='02'O},
        {header:='AA'O,data:='03'O}
    }
}

type set S2 {
    R2 field1,
    R3 field2,
    R1list field3
}
with {variant (field3) "REPEATABLE(no)"}

//Only the example1 is a valid encoded value for S2, because
```

Prepared (Subject resp) ETHBAAT Jeno Balasko		No. 2/198 17-CRL 113 200/5 Uen		
Approved (Document resp) ETHLEL Elemer Lelik	Checked ETHGRY	Date 2015-05-15	Rev C	Reference

//the elements of the field3 must be grouped together.

#### 4.23.4.7 Obsolete Attributes

This section describes the obsolete attributes. These attributes are kept for compatibility reason. The usage of the obsolete attributes is not recommended in new developments.

### BITORDERINOCTET

The attribute has the same meaning and syntax as `BITORDER` (see section [0](#)). In new developments only the attribute `BITORDER` may be used.

### TOplevel BITORDER

Attribute syntax: `TOplevel( BITORDER(<parameter>))`

Parameters allowed:     `msb`  
                          `lsb`

Default value: `msb`

Can be used with:        a toplevel type.

Description:    This attribute specifies the order of the bits within an octet. When set to `lsb`, the first bit sent will be the least significant bit of the original byte.

Comment:

Example:

```
type record WholePDU {
    Field1 field1,
    Field2 field2
}
with { variant "TOplevel( BITORDER(lsb) )" }
const WholePDU c_pdu := {
    '12'O,
    '12'O
}

//Encoding of c_pdu will result in '4848'O.
```

#### 4.23.5 TTCN-3 Types and Their Attributes

This section lists the TTCN-3 types along with the attributes allowed to be used with the types.

Prepared (Subject resp) ETHBAAT Jeno Balasko		No. 2/198 17-CRL 113 200/5 Uen		
Approved (Document resp) ETHLEL Elemer Lelik	Checked ETHGRY	Date 2015-05-15	Rev C	Reference

## BITSTRING

**Coding:** The `bitstring` is represented by its binary value. The LSB of the binary form of a `bitstring` is concatenated to the LSB of the `bitfield`. If the length of the `bitstring` is shorter than the specified `FIELDLENGTH`, aligning is governed by the attribute `ALIGN`.

The `FIELDLENGTH` default value for `bitstring` type is variable.

**Attributes allowed:**

- `ALIGN` [\(0\)](#),
- `BITORDER` [\(0\)](#),
- `BITORDERINFIELD` [\(0\)](#),
- `BYTEORDER` [\(0\)](#),
- `FIELDLENGTH` [\(0\)](#)

### Example:

```
//Example number 1): variable length bitstring
const bitstring c_mystring:='1011000101'B

//The resulting bitfield: 1011000101

//The encoding will have the following result:
//      11000101
//      .....10

//Example number 2): fixed length bitstring
type bitstring BIT7 with { variant "FIELDLENGTH(7)" }

const BIT7 c_ourstring:='0101'B

//The resulting bitfield: 0000101

//Example number 3): left aligned bitstring
type bitstring BIT7align with {
    variant "FIELDLENGTH(7), ALIGN(left)" }

const BIT7align c_yourstring:='0101'B

//The resulting bitfield: 0101000
```

## BOOLEAN

**Coding:** The boolean value `true` coded as `'1'B`, the boolean value `false` coded as `'0'B`. If `FIELDLENGTH` is specified, the given number of ones (`true`) or zeros (`false`) is coded. If the decoded `bitfield` is zero the decoded value will be `false` otherwise `true`. The default `FIELDLENGTH` for `boolean` type is 1.

**Attributes allowed:** `FIELDLENGTH` [\(0\)](#)

### Examples:

```
//Example number 1): boolean coded with default length
const boolean c_myvar:=true

//The resulting bitfield: 1
```

Prepared (Subject resp) ETHBAAT Jeno Balasko		No. 2/198 17-CRL 113 200/5 Uen		
Approved (Document resp) ETHLEL Elemer Lelik	Checked ETHGRY	Date 2015-05-15	Rev C	Reference

```
//Example number 2): boolean coded with fixed length
type boolean Mybool with { variant "FIELDLENGTH(8)" }

const Mybool c_ourvar:=true

//The resulting bitfield: 11111111
```

## CHARSTRING

**Coding:** The characters are represented by their ASCII binary value. The first character is put into the first octet of the bitfield. The second character is put into the second octet of the bitfield and so on. Thus, the first character is put first into the buffer. If the actual value of `charstring` is shorter than the specified `FIELDLENGTH`, aligning is governed by the attribute `ALIGN`. The default `FIELDLENGTH` for `bitstring` type is variable. The `FIELDLENGTH` is measured in chars.

**Attributes allowed:** `ALIGN` [\(0\)](#),  
`BITORDER` [\(0\)](#),  
`BITORDERINFIELD` [\(0\)](#),  
`BYTEORDER` [\(0\)](#),  
`FIELDLENGTH` [\(0\)](#)

### Examples:

```
//Example number 1): variable length charstring
const charstring c_mystring:="Hello"

//The resulting bitfield: 01101111 01101100 01101100
//                        01100101 01001000

//The encoding will have the following result:
// 01001000 "H"
// 01100101 "e"
// 01101100 "l"
// 01101100 "l"
// 01101111 "o"

//Example number 2): fixed length charstring
type charstring CHR6 with { variant "FIELDLENGTH(6)" }
const CHR6 c_yourstring:="Hello"
//The resulting bitfield: 00000000 01101111 01101100 01101100
//                        01100101 01001000
//The encoding will have the following result:
// 01001000 "H"
// 01100101 "e"
// 01101100 "l"
// 01101100 "l"
// 01101111 "o"
// 00000000 " "
```

Prepared (Subject resp) ETHBAAT Jeno Balasko		No. 2/198 17-CRL 113 200/5 Uen		
Approved (Document resp) ETHLEL Elemer Lelik	Checked ETHGRY	Date 2015-05-15	Rev C	Reference

```
//Example number 3): left aligned charstring
type charstring CHR6align with {
    variant "FIELDLENGTH(6), ALIGN(left)" }

const CHR6align c_string:="Hello"

//The resulting bitfield: 01101111 01101100 01101100 01100101
//                        01001000 00000000

//The encoding will have the following result:
// 00000000 " "
// 01001000 "H"
// 01100101 "e"
// 01101100 "l"
// 01101100 "l"
// 01101111 "o"
```

## ENUMERATED

**Coding:** The `enumerated` type is coded as an integer value. This numerical value is used during encoding. The default `FIELDLENGTH` for `enumerated` type is the minimum number of bits required to display the highest enumerated value.

**Attributes allowed:** `BITORDER`([0](#)),  
`BITORDERINFIELD` ([0](#)),  
`BYTEORDER` ([0](#)),  
`COMP` ([0](#)),  
`FIELDLENGTH` ([0](#))

### Example:

```
type enumerated Enumm {zero, one, two, three, four, five}

const Enumm myenum:=two

//The maximum enumerated value: 5 (five)
//Minimum 3 to represent 5.
//The FIELDLENGTH will be 3
//The resulting bitfield: 010

type enumerated Enum { zero(2), one(23), two(4), three(1), four(0), five(5) }

const Enum c_myenum:=two

//The maximum enumerated value: 23 (one)
//Minimum 5 bits are needed to represent 23.
//The FIELDLENGTH will be 5
//The resulting bitfield: 00010
```

## FLOAT

**Coding:** The `float` value is represented according to IEEE 754 standard. The `FORMAT` attribute specifies the number of the bits used in exponent and mantissa.

IEEE754 double: The float value is encoded as specified in IEEE754 standard using 1 sign bit, 11

Prepared (Subject resp) ETHBAAT Jeno Balasko		No. 2/198 17-CRL 113 200/5 Uen		
Approved (Document resp) ETHLEL Elemer Lelik	Checked ETHGRY	Date 2015-05-15	Rev C	Reference

exponent bits and 52 bits for mantissa.

IEEE754 float: The float value is encoded as specified in IEEE754 standard using 1 sign bit, 8 exponent bits and 23 bits for mantissa.

The default FORMAT for float is IEEE754 double.

Attributes allowed: BITORDER [\(0\)](#),  
BITORDERINFIELD [\(0\)](#),  
BYTEORDER [\(0\)](#),  
FORMAT [\(0\)](#)

#### Example:

```
//S - sign bit
//E - exponent bits
//M - mantissa bits

//Example number 1): single precision float
type float SingleFloat
with {
    variant "FORMAT(IEEE754 float)"
}

const SingleFloat c_float:=1432432.125

//The resulting bitfield: 10000001 11011011 10101110 01001001
//                        MMMMMMMM MMMMMMMM EMMMMMMM SEEEEEEE

//The encoding will have the following result:
// 01001001 SEEEEEEE
// 10101110 EMMMMMMM
// 11011011 MMMMMMMM
// 10000001 MMMMMMMM

//The encoding will result in the octetstring '49AEDB81'O

//Example number 2): double precision float
type float DoubleFloat
with {
    variant "FORMAT(IEEE754 double)"
}

const DoubleFloat c_floatd:=1432432.112232

//The resulting bitfield:
//82 3c bb 1c70 db 35 41
//10000010 00111100 10111011 00011100
//01110000 11011011 00110101 01000001
//MMMMMMMM MMMMMMMM MMMMMMMM MMMMMMMM
//MMMMMMMM MMMMMMMM EEEEEMMM SEEEEEEE

//The encoding will have the following result:
// 01000001 SEEEEEEE
//      00110101 EEEEEMMM
// 11011011 MMMMMMMM
//      01110000 MMMMMMMM
// 00011100 MMMMMMMM
// 10111011 MMMMMMMM
// 00111100 MMMMMMMM
// 10000010 MMMMMMMM

//The encoding will result in the octetstring
// '4135DB701CBB3C82'O
```

Prepared (Subject resp) ETHBAAT Jeno Balasko		No. 2/198 17-CRL 113 200/5 Uen		
Approved (Document resp) ETHLEL Elemer Lelik	Checked ETHGRY	Date 2015-05-15	Rev C	Reference

## HEXSTRING

**Coding:** The hexadecimal digit is represented by its binary value. The first hexadecimal digit is put into the lower nibble of first octet of the bitfield. The second hexadecimal digit is put into the higher nibble of first octet of the bitfield. The 3<sup>rd</sup> hexadecimal digit is put into the lower nibble of second octet of bitfield and so on. Thus, the first hexadecimal digit is put first into the buffer. Is the actual length of hexstring shorter than the specified by FIELDLENGTH, aligning is governed by the attribute ALIGN.

The default FIELDLENGTH value for hexstring type is variable.

In this case, FIELDLENGTH is measured in hexdigits.

**Attributes allowed:** ALIGN [\(0\)](#),  
BITORDER [\(0\)](#),  
BITORDERINFIELD [\(0\)](#),  
BYTEORDER [\(0\)](#),  
FIELDLENGTH [\(0\)](#)

### Example:

```
//Example number 1): variable length hexstring
const hexstring c_mystring:='5AF'H

//The resulting bitfield: 1111 10100101

//The encoding will have the following result:
// 10100101 A5
// ....1111 .F

//Example number 2): fixed length hexstring
type hexstring HEX4 with { variant "FIELDLENGTH(4)" }

const HEX4 c_yourstring:='5AF'H

//The resulting bitfield: 00001111 10100101

//The encoding will have the following result:
// 10100101 A5
// 00001111 0F

//Example number 3): left aligned hexstring
type hexstring HEX4align with {
    variant "FIELDLENGTH(4), ALIGN(left)" }

const HEX4align c_ourstring:='5AF'H

//The resulting bitfield: 11111010 01010000

//The encoding will have the following result:
// 01010000 50
// 11111010 FA
```

Prepared (Subject resp) ETHBAAT Jenö Balasko		No. 2/198 17-CRL 113 200/5 Uen		
Approved (Document resp) ETHLEL Elemer Lelik	Checked ETHGRY	Date 2015-05-15	Rev C	Reference

## INTEGER

**Coding:** The `LSB` of the binary form of an `integer` is concatenated to the `LSB` of the bitfield. The value of the attribute `COMP` determines how the value of an `integer` type will be coded to binary form. The integer is always of fixed length and fills the space specified by `FIELDLENGTH`.

The default value of `FIELDLENGTH` for integer is 8 bit.

The `ALIGN` attribute has no meaning for integer.

**Attributes allowed:** `BITORDER` ([0](#)),  
`BITORDERINFIELD` ([0](#)),  
`BYTEORDER` ([0](#)),  
`COMP` ([0](#)),  
`FIELDLENGTH` ([0](#))

### Example:

```
//Example number 1)
type integer Int12
  with{ variant "FIELDLENGTH(12)"}

const Int12 c_myint:=1052

//The resulting bitfield is 010000011100
//The encoding will have the following result:
// 00011100
// ....0100
//The same result represented as octetstring: '1C.4'O
```

```
//Example number 2)
type integer Int12sg
  with{ variant "FIELDLENGTH(12), COMP(signbit)"}

const Int12sg c_mysignedint:=-1052

//The resulting bitfield: 110000011100
//The encoding will have the following result:
// 00011100
// ....1100
//The same result represented as octetstring: '1C.C'O
```

```
//Example number 3)
type integer Int12c
  with{ variant "FIELDLENGTH(12), COMP(2scompl)"}

const int12c c_hisint:=-1052

//The resulted bitfield: 101111100111
//The encoding will have the following result:
// 11100111
// ....1011
//The same result represented as octetstring: 'E7.B'O
```

Prepared (Subject resp) ETHBAAT Jenő Balasko		No. 2/198 17-CRL 113 200/5 Uen		
Approved (Document resp) ETHLEL Elemer Lelik	Checked ETHGRY	Date 2015-05-15	Rev C	Reference

## OCTETSTRING

**Coding:** The octets are represented by their binary value. The first octet is put into first octet of bitfield. The second octet is put second octet of bitfield and so on. Thus, the first octet is put first into the buffer. If the length of the `octetstring` is shorter than the specified `FIELDLENGTH`, aligning is governed by the attribute `ALIGN`.

The default `FIELDLENGTH` value for `octetstring` type is variable.

In this case, `FIELDLENGTH` is measured in octets.

**Attributes allowed:** `ALIGN` (0),  
`BITORDER` (0),  
`BITORDERINFIELD` (0),  
`BYTEORDER` (0),  
`FIELDLENGTH` (0)

### Example:

**//Example number 1): variable length octetstring**  
`const octetstring c_mystring:='25AF'O`

`//The resulting bitfield: 10101111 00100101`

`//The encoding will have the following result:  
// 00100101 25  
// 10101111 AF`

**//Example number 2): fixed length octetstring**  
`type octetstring OCT3 with { variant "FIELDLENGTH(3)" }`

`const OCT3 c_yourstring:='25AF'H`

`//The resulting bitfield: 00000000 10101111 00100101`

`//The encoding will have the following result:  
// 00100101 25  
// 10101111 AF  
// 00000000 00`

**//Example number 3): left aligned octetstring**  
`type octetstring OCT3align with {  
variant "FIELDLENGTH(3), ALIGN(left)" }`

`const OCT3align c_string:='25AF'H`

`//The resulting bitfield: 10101111 00100101 00000000`

`//The encoding will have the following result:  
// 00000000 00  
// 00100101 25  
// 10101111 AF`

## SET

**Encoding:** During encoding the fields present are encoded one by one. If `TAG` is specified for one field, the value of the key field is checked for a valid value. If a valid value is not

Prepared (Subject resp) ETHBAAT Jeno Balasko		No. 2/198 17-CRL 113 200/5 Uen		
Approved (Document resp) ETHLEL Elemer Lelik	Checked ETHGRY	Date 2015-05-15	Rev C	Reference

found, the value of the key field will be substituted with a valid key value.

Decoding: The fields can be received in any order. If TAG is specified, the value of the key field identifies the fields.

If TAG is not specified for any field, the decoder tries to decode a field. If the decoding is successful, the decoder assumes that the field was received.

The matching algorithm is the following: First try to identify the received fields by TAGs; if it fails, try to decode the fields; if it fails and OTHERWISE is specified in TAG, try that field; if it fails: unknown field is received. If all mandatory fields have already been decoded, then the set is successfully decoded, else the decoding of set has failed.

## RECORD

Encoding: The fields present are encoded one by one. The value of length and pointer fields are calculated and substituted.

If TAG, CROSSTAG or PRESENCE are specified for one field, the value of the key field is checked for a valid value. If a valid value is not found, the value of key field will be substituted with a valid key value. Finally, the extension bits are set.

Decoding: Fields are decoded one by one. The presence of optional fields is determined by the attributes TAG, PRESENCE, by extension bits and by the value of the length field. The chosen field of union is determined by CROSSTAG, if present. The value of pointer field is used to determine the beginning of the pointed field. Have all of the mandatory fields been received and successfully decoded, the decoding of the record is successful.

## RECORD OF, SET OF

Encoding: The elements of record of or set of are encoded one by one. Finally, the extension bits are set, if needed.

Decoding: The items of record of or set of are decoded one by one. The number of items is determined by the attribute FIELDLENGTH, by extension bits or the number of available bits in buffer. The decoding of record of or

Prepared (Subject resp) ETHBAAT Jeno Balasko		No. 2/198 17-CRL 113 200/5 Uen		
Approved (Document resp) ETHLEL Elemer Lelik	Checked ETHGRY	Date 2015-05-15	Rev C	Reference

set of is successful if at least one item has been decoded.

## UNION

**Encoding:** The chosen field will be encoded according to its own encoding rules. If TAG is specified for this field, the value of the key field is checked for a valid value. If a valid value is not found, the value of the key field will be substituted with a valid key value.

**Decoding:** The decoder tries to identify the received union field. If TAG is present, the decoder uses the value of the key fields to identify the fields. If TAG is not present, the decoder tries to decode the fields and if it succeeds, the decoder assumes that field is received. If the decoding of field is not successful, the decoder checks the next field. The decoding of the union will be unsuccessful if none of the fields can be decoded.

### Examples:

```
type record Rec{
    OCT1 key,
    OCT1 values
}

type union MyUnion{
    Rec field1,
    Rec field2,
    Rec field3
} with { variant "TAG( field1,{key = '56'O, key='FF'};
                    field2, key = 'FF';
                    field3,{key = 'A4'O, key = '99'O})"
}
```

#### //Example number 1): successful encoding

```
const MyUnion c_PDU:={
    field1:={ key:='7A'O, values:='B2'O}
}

//Chosen field: field1
//Value of key field: '7A'O; valid
//No substitution will take place.
//The encoding will have the following result:
// 01111010 7A
// 10110010 B2
```

#### //Example number 2): key field substituted

```
const MyUnion c_PDU2:={
    field1:={ key:='00'O, values:='B2'O}
}

//Chosen field: field1
//Value of key field: '00'O not valid
//The value of key field will be substituted with:'56'O
//The encoding will have the following result:
// 01010110 56
// 10110010 B2
```

Prepared (Subject resp) ETHBAAT Jeno Balasko		No. 2/198 17-CRL 113 200/5 Uen

## 4.24 TEXT Encoder and Decoder

The TEXT encoder and decoder are general purpose functionalities developed originally for handling verbose and tokenized protocols.

The encoder converts abstract TTCN-3 structures (or types) into a bitstream suitable for serial transmission. The decoder, on the contrary, converts the received bitstream into values of abstract TTCN-3 structures.

TITAN provides a special encoding scheme for coding elements into a textual representation. This is called TEXT and is used like `encoding "TEXT"`.

This section covers the attributes controlling the coding process ([4.24.1](#)) and BNF specification of the attributes ([4.24.2](#)).

Error encountered during the encoding or decoding process are handled as defined in section “Setting error behavior” in [\[16\]](#).

### 4.24.1 Attributes

An `attribute` determines coding and encoding rules.

Note the section 27.5 of the TTCN-3 standard ([\[1\]](#)) states that an `attribute` is used to refine the current encoding scheme defined with the keyword `encode`. Because of backward compatibility the presence of the `encode` attribute is not required, but might result in a compile time warning (which in the future might turn into an error).

#### BEGIN

**Role:** The `BEGIN` attribute defines the leading token of the type.

**Format:** `BEGIN(token_to_encode,  
<matching_exp>, <modifier>)`

**Description:** The attribute defines the leading token of the type. This token defines the beginning of the value of the type and will be written into the encoded string before the value of the `type` is encoded. `BEGIN` can be used with any type.

**Parameters:** `token_to_encode`  
The token is used during encoding. Mandatory.

`matching_exp`  
This TTCN-3 character pattern is used during decoding to identify the leading token of the type. The format of the parameter is described in clause B.1.5 of the TTCN-3 standard ([\[1\]](#)). This parameter is optional; when omitted,

Prepared (Subject resp) ETHBAAT Jeno Balasko		No. 2/198 17-CRL 113 200/5 Uen		
Approved (Document resp) ETHLEL Elemer Lelik	Checked ETHGRY	Date 2015-05-15	Rev C	Reference

the parameter `token_to_encode` will be used as the matching pattern.

`modifier`

Modifies the behavior of the matching algorithm. Optional parameter. When omitted the default value will be used.

The available modifiers:

– `case_sensitive`

The matching is case sensitive. Default value.

– `case_insensitive`

The matching is case insensitive.

#### Example:

```
//SIP header Subject header:
```

```
type record Subject{
    charstring subject_value
}
with { variant "BEGIN('Subject: ',
    (Subject[ \t]#(,):[ \t]#(,))|"
    "(s[ \t]#(,):[ \t]#(,))',
    case_insensitive)"
}

var Subject v_subj:= "the_subject";

//The encoded string will be: "Subject: the subject"
//The decoder will accept the long (Subject: the subject)
//and the short (s: the subject) format regardless
//of the case of the character of the header.
```

## END

**Role:** The `END` attribute defines the closing token of the type.

**Format:** `END(token_to_encode, <matching_exp>, <modifier>)`

**Description:** The attribute defines the closing token of the type. This token defines the end of the value of the type and will be written into the encoded string after the encoded value of the type.  
`END` can be used with any type.

**Parameters:** `token_to_encode`  
The token used during encoding. Mandatory.

`matching_exp`

This TTCN-3 character pattern is used during decoding to identify the leading token of the type. The format of the parameter is described in clause B.1.5 of the TTCN-3 standard ([\[1\]](#)). This parameter is optional; when omitted, the `token_to_encode` will be used as matching pattern.

`modifier`

Prepared (Subject resp) ETHBAAT Jeno Balasko		No. 2/198 17-CRL 113 200/5 Uen		
Approved (Document resp) ETHLEL Elemer Lelik	Checked ETHGRY	Date 2015-05-15	Rev C	Reference

Modifies the behavior of the matching algorithm. Optional parameter. When omitted, the default value will be used. The available modifiers:

- `case_sensitive`  
The matching is case sensitive. Default value.
- `case_insensitive`  
The matching is case insensitive.

Example:  
//SIP header Subject header:

```
type record Subject{
  charstring subject_value
}
with { variant "BEGIN('Subject: ','
  (Subject[ \t]#(,):[ \t]#(,))|"
    "(s[ \t]#(,):[ \t]#(,))',
    case_insensitive)";
  variant "END('\'\\r\\n','([\\r])|([\\r\\n]))'"
}
var Subject v_subj:= "the_subject";

//The encoded string will be: "Subject: the_subject\\r\\n"
//The decoder will accept both "Subject: the\\_subject\\r\\n" and //"Subject:
the_subject\\r" format.
```

SEPARATOR

Role: The attribute SEPARATOR defines the field separator token of the type.

Format: SEPARATOR(token to encode, <matching exp>,<modifier>)

Description: The attribute defines the field separator token of the type. This token separates the value of fields and will be written into the encoded string between the fields of the type. SEPARATOR can be used with any type.

Parameters: token\_to\_encode  
The token used during encoding. Mandatory.

matching\_exp  
This TTCN-3 character pattern is used during decoding to identify the leading token of the type. The format of the parameter is described in clause B.1.5 of the TTCN-3 standard ([11](#)). Optional parameter. When omitted, the token to encode will be used as matching pattern.

modifier  
Modifies the behavior of the matching algorithm. Optional parameter. When omitted, the default value will be used. The available modifiers:

- `case_sensitive`  
The matching is case sensitive. Default value.

Prepared (Subject resp) ETHBAAT Jeno Balasko		No. 2/198 17-CRL 113 200/5 Uen		
Approved (Document resp) ETHLEL Elemer Lelik	Checked ETHGRY	Date 2015-05-15	Rev C	Reference

– case\_insensitive  
The matching is case insensitive.

#### Example:

```
type record Rec_1{
    charstring field_1,
    charstring field_2
}
with {
    variant "BEGIN('Header: ')"
    variant "SEPARATOR(';') "
}

var Rec_1 v_rec:={field1:="value_field1",
                  field2:="value_field2"}

//The encoded will result in the string:
//"Header: value_field1; value_field2"
```

## TEXT\_CODING

Role:	The attribute TEXT_CODING defines the encoding and decoding rules of the value
Format:	TEXT_CODING(encoding_rule, <decoding_rule>,<matching_exp>,<modifier>)
Description:	The attribute controls the encoding and the decoding of the values.
Parameters:	<p>encoding_rule  Controls the encoding of the value. For syntax see the two tables below.</p> <p>decoding_rule  Controls the decoding of the value. For syntax see the two tables below.</p> <p>matching_exp  TTCN–3 character pattern, used during decoding to identify the value of the type. The format of the parameter is described in clause B.1.5 of the TTCN–3 standard (<a href="#">[1]</a>). Optional parameter.</p> <p>modifier  Modifies the behavior of the matching algorithm. Optional parameter. When omitted, the default value will be used. The available modifiers:</p> <ul style="list-style-type: none"> <li>– case_sensitive  The matching is case sensitive. Default value.</li> <li>– case_insensitive  The matching is case insensitive.</li> </ul>

Prepared (Subject resp) ETHBAAT Jeno Balasko		No. 2/198 17-CRL 113 200/5 Uen		
Approved (Document resp) ETHLEL Elemer Lelik	Checked ETHGRY	Date 2015-05-15	Rev C	Reference

attr	Description	Parameter	Default value
length	Determines the length of the coded value.	value	number of characters of value
convert	Converts string values to lower or upper case during encoding or decoding.	lower_case   upper_case	no conversion
just	If the string is shorter than the value defined by the length attribute, just controls the justification of the value.	left   right   center	left
leading0	Controls the presence of the leading zeros of the coded integer value.	true   false	false
repeatable	The attribute repeatable controls whether the element of the record or set of can be mixed with other elements of the set or they are grouped together.	true   false	false

### Example:

```
//Example number 1): integer with leading zero
type integer My_int with {
  variant "TEXT_CODING(length=5;leading0=true)"
}

var My_int v_a:=4;
// The encoded value: '00004'

//Example number 2): integer without leading zero
type integer My_int2 with {
  variant "TEXT_CODING(length=5)"
}
var My_int2 v_aa:=4;

// The encoded value: ' 4'

//Example number 3): character string
type charstring My_char with {
  variant "TEXT_CODING(length=5)"
}

var My_char v_aaa:='str';
// The encoded value: ' str'

                  / ("repeatable=" ("true"/"false") )

enc-enu         = enumerated ":" encode-token

enc-bool        = ("true:" encode-token) / ("true:" encode-token)

dec-enum        = enumerated ":" "{" [match-expr] [COMMA modifier] "}"

dec-bool        = (true ":" "{" [match-expr] [COMMA modifier] "}")
                  / (false ":" "{" [match-expr] [COMMA modifier] "}")
```

## 4.25 XML Encoder and Decoder

The XML encoder and decoder are handling XML-based protocols. The encoder converts abstract TTCN-3 structures (or types) into an XML representation. The decoder converts the XML data into values of abstract TTCN-3 structures.

### 4.25.1 General Rules and Restrictions

The TTCN-3 standard defines a mechanism using attributes to define encoding variants. The attributes concerning the XML encoding are standardized in [4] (annex B of the standard lists the attributes and their effects).

Faults in the XML encoding/decoding process are set to error by default, but it can be modified with the `errorbehavior` TTCN-3 attribute. ([Codec error handling](#))

### 4.25.2 Attributes

The following sections describe the TTCN-3 attributes that influence the XML coding.

Prepared (Subject resp) ETHBAAT Jenö Balasko		No. 2/198 17-CRL 113 200/5 Uen		
Approved (Document resp) ETHLEL Elemer Lelik	Checked ETHGRY	Date 2015-05-15	Rev C	Reference

### Any element

Attribute syntax: `anyElement [ except ( 'freetext' | unqualified ) | from [unqualified,] [ { 'freetext' , } 'freetext' ] ]`

Applicable to (TTCN-3) Fields of structured types generated for the XSD *any* element

Description One TTCN-3 attribute shall be generated for each field corresponding to an XSD any element. The freetext part(s) shall contain the URI(s) identified by the namespace attribute of the XSD any element. The namespace attribute may also contain wildcard. They shall be mapped as given in the following table:

Table 9 XSD namespace attributes

<i>Value of the XSD namespace attribute</i>	<b>Except or from clause in the TTCN-3 attribute</b>	<b>Remark</b>
<b>##any</b>	<i>&lt;nor except neither from clause present&gt;</i>	
<b>##local</b>	from unqualified	
<b>##other</b>	except ' <i>&lt;target namespace of the ancestor schema element of the given any element&gt;</i> '	Also disallows unqualified elements, i.e. elements without a target namespace
<b>##other</b>	except unqualified	In the case no target namespace is ancestor schema element of the given any element
<b>##targetNamespace</b>	from ' <i>&lt;target namespace of the ancestor schema element of the given any element &gt;</i> '	
<b>"http://www.w3.org/1999/xhtml ##targetNamespace"</b>	from 'http://www.w3.org/1999/xhtml', ' <i>&lt;target namespace of the ancestor schema element of the given any element &gt;</i> '	

The abstract value of the field will be encoded as an XML element in place of an XML element that would be generated for the field (ignoring the name of the field). During decoding, the abstract value of the field will contain the entire XML element.

### Example

```
type record AEProduct {
  charstring name,
  integer price,
  universal charstring info
}
with {
  variant (info) "anyElement from 'http://www.example.com/A', "
  "'http://www.example.com/B', unqualified"
}
```

Prepared (Subject resp) ETHBAAT Jeno Balasko		No. 2/198 17-CRL 113 200/5 Uen		
Approved (Document resp) ETHLEL Elemer Lelik	Checked ETHGRY	Date 2015-05-15	Rev C	Reference

```
const AEProduct aep := {
  name := "Trousers",
  price := 20,
  info := "<xyz:color xmlns:xyz='http://www.example.com/A' "
available="true">red</xyz:color>"
}

/* XML encoding:
<AEProduct>
  <name>Trousers</name>
  <price>20</price>
  <xyz:color xmlns:xyz='http://www.example.com/A'
available="true">red</xyz:color>
</AEProduct>
*/
```

## Any attributes

Attribute syntax: `anyAttributes[ except 'freetext' | from [unqualified , ] { 'freetext', } 'freetext' ]`

Applicable to (TTCN-3) Fields of structured types generated for the XSD *anyAttribute* element

Description This TTCN-3 attribute can be applied to a field which is of type **record of universal charstring**. Each component shall contain a valid XML attribute (name/value pair), optionally preceded by a namespace identifier (URI). The encoder shall remove the URI and insert it as a namespace declaration into the enclosing XML element, followed by the content of the **universal charstring** as an XML attribute. The decoder should recover each attribute into a component of the **record of**, preceded by its namespace URI if applicable. The mapping of namespaces behaves in the same way as the *anyElement* TTCN-3 attribute.

## Example

```
type record of universal charstring AttrList;
type record AAProduct {
  AttrList info,
  charstring name,
  integer price
}
with {
  variant (info) "anyAttributes from 'http://www.example.com/A', "
  "'http://www.example.com/B', unqualified"
}

const AAProduct aap := {
  info := {
    "http://www.example.com/A size=""small"",
    "http://www.example.com/B color=""red"",
    "available=""yes""},
  name := "Trousers",
  price:= 20
}
```

Prepared (Subject resp) ETHBAAT Jeno Balasko		No. 2/198 17-CRL 113 200/5 Uen		
Approved (Document resp) ETHLEL Elemer Lelik	Checked ETHGRY	Date 2015-05-15	Rev C	Reference

```

/* XML encoding:
<AAPProduct
  xmlns:b0="http://www.example.com/A" b0:size="small"
  xmlns:b1="http://www.example.com/B" b1:color="red" available="yes">
  <name>Trousers</name>
  <price>20</price>
</AAPProduct>
*/

```

## Attribute

Attribute syntax:            attribute

Applicable to (TTCN-3)    Top-level type definitions and fields of structured types generated for XSD *attribute* elements.

Description                This encoding instruction causes the instances of the TTCN-3 type or field to be encoded and decoded as attributes.

Comment                    Titan currently requires during decoding that attributes are present in the same order as they are declared in the enclosing record/set.

## Example

```

type charstring Color
with {
  variant "attribute"
}
type record Product {
  Color      color,
  charstring material,
  charstring name,
  integer    price
}
with {
  variant (available) "attribute"
}

const Product shoes := {
  color := "blue",
  material := "suede",
  name := "Shoes",
  price:= 25
}
/* XML encoding
<Product color="blue" material="suede">
  <name>Shoes</name>
  <price>25</price>
</Product>
*/

```

## AttributeFormQualified

Attribute syntax:        attributeFormQualified

Prepared (Subject resp) ETHBAAT Jenö Balasko		No. 2/198 17-CRL 113 200/5 Uen		
Approved (Document resp) ETHLEL Elemer Lelik	Checked ETHGRY	Date 2015-05-15	Rev C	Reference

### Applicable to (TTCN-3) Modules

**Description** This encoding instruction cause names of XML attributes that are instances of TTCN-3 definitions in the given module to be encoded as qualified names. At decoding time qualified names are expected as valid attribute names.

### Control namespace identification

**Attribute syntax:** controlNamespace '*freetext*' prefix '*freetext*'

### Applicable to (TTCN-3) Module

**Description** The control namespace is the namespace to be used for the type identification attributes and schema instances (e.g. in the special XML attribute value "xsi:nil". It shall be specified globally, with an encoding instruction attached to the TTCN-3 module. The first *freetext* component identifies the namespace (normally '<http://www.w3.org/2001/XMLSchema-instance>' is used), the second *freetext* component identifies the namespace prefix (normally 'xsi' is used).

**Example** Please see the example for nillable elements, section 0 below, for example usage of controlNamespace.

### Default for empty

**Attribute syntax:** defaultForEmpty as '*freetext*'

**Applicable to (TTCN-3)** TTCN-3 components generated for XSD *attribute* or *element* elements with a *fixed* or *default* attribute.

**Description** The '*freetext*' component shall designate a valid value of the type to which the encoding instruction is attached to. This encoding instruction has no effect on the encoding process and causes the decoder to insert the value specified by *freetext* if the corresponding attribute or element is omitted in the received XML document.

### Example

```
type record DFEProduct {
    charstring color,
    charstring name,
    float price,
    charstring currency
}
with {
    variant (color) "attribute";
    variant (currency) "defaultForEmpty as 'US Dollars'";
}
```

Prepared (Subject resp) ETHBAAT Jeno Balasko		No. 2/198 17-CRL 113 200/5 Uen		
Approved (Document resp) ETHLEL Elemer Lelik	Checked ETHGRY	Date 2015-05-15	Rev C	Reference

```
const DFEPProduct rval := {  
    color    := "red",  
    name     := "shirt",  
    price    := 12.33,  
    currency := "US Dollars"  
}  
  
/* The following XML fragment will be decoded to the value of rval:  
<DFEPProduct color="red">  
  <name>shirt</name>  
  <price>12.33</price>  
  <currency/>  
</DFEPProduct>  
*/
```

## Element

Attribute syntax:	element
Applicable to (TTCN-3)	Top-level type definitions generated for XSD <i>element</i> elements that are direct children of a <i>schema</i> element.
Description	This encoding instruction causes the instances of the TTCN-3 type to be encoded and decoded as XML elements.
Comment	This is the default behaviour. TTCN-3 types are encoded as elements unless altered by an encoding instruction. This encoding instruction can be used to cancel that effect.

## ElementFormQualified

Attribute syntax:	elementFormQualified
Applicable to (TTCN-3)	Modules
Description	This encoding instruction causes tags of XML local elements that are instances of TTCN-3 definitions in the given module to be encoded as qualified names. At decoding time qualified names are expected as valid element tags names.

## Embed values

Attribute syntax:	embedValues
Applicable to (TTCN-3)	TTCN-3 record types generated for XSD <i>complexType</i> -s and <i>complexContent</i> -s with the value of the <i>mixed</i> attribute "true".

Prepared (Subject resp) ETHBAAT Jenö Balasko		No. 2/198 17-CRL 113 200/5 Uen		
Approved (Document resp) ETHLEL Elemer Lelik	Checked ETHGRY	Date 2015-05-15	Rev C	Reference

## Description

The encoder shall encode the record type to which this attribute is applied in a way that produces the same result as the following procedure: first a partial encoding of the record is produced, ignoring the `embed_values` field. The first string of the `embed_values` field (the first record of element) shall be inserted at the beginning of the partial encoding, before the start-tag of the first XML element (if any). Each subsequent string shall be inserted between the end-tag of the XML element and the start-tag of the next XML element (if any), until all strings are inserted. In the case the maximum allowed number of strings is present in the TTCN-3 value (the number of the XML elements in the partial encoding plus one) the last string will be inserted after end-tag of the last element (to the very end of the partial encoding). The following special cases apply:

- a) At decoding, strings before, in-between and following the XML elements shall be collected as individual components of the `embed_values` field. If no XML elements are present, and there is also a `defaultForEmpty` encoding instruction on the sequence type, and the encoding is empty, a decoder shall interpret it as an encoding for the *freetext* part specified in the `defaultForEmpty` encoding instruction and assign this abstract value to the first (and only) component of the `embed_values` field.
- b) If the type also has the `useNil` encoding instruction and the optional component is absent, then the `embedValues` encoding instruction has no effect.
- c) If the type has a `useNil` encoding instruction and if a decoder determines, by the absence of a `nil` identification attribute (or its presence with the value `false`) that the optional component is present, then item a) above shall apply.

## Comment

Titan currently does not decode the values of the `embed_values` member. They will appear as empty strings.

## Example

```
type record EmbProduct {
  record of universal charstring embed_values,
  universal charstring companyName,
  universal charstring productColor,
  universal charstring productName
}
with {
```

Prepared (Subject resp) ETHBAAT Jeno Balasko		No. 2/198 17-CRL 113 200/5 Uen		
Approved (Document resp) ETHLEL Elemer Lelik	Checked ETHGRY	Date 2015-05-15	Rev C	Reference

```
    variant "embedValues"
  }

  const EmbProduct rval := {
    embed_values := {"My Company", "produces", "", "which is very popular"},
    companyName := "ABC",
    productColor := "red",
    productName := "shirt"
  }

  /* XML encoding
  <EmbProduct>My
  Company<companyName>ABC</companyName>produces<productColor>red</productColor>
  <productName>shirt</productName>which is very popular</EmbProduct>
  */
```

## Form

Attribute syntax: form as (qualified | unqualified)

Applicable to (TTCN-3) Top-level type definitions generated for XSD *attribute* elements and fields of structured type definitions generated for XSD *attribute* or *element* elements.

Description This encoding instruction designates that names of XML attributes or tags of XML local elements corresponding to instances of the TTCN-3 type or field of type to which the form encoding instruction is attached, shall be encoded as qualified or unqualified names respectively and at decoding qualified or unqualified names shall be expected respectively as valid attribute names or element tags.

## List

Attribute syntax: list

Applicable to (TTCN-3) Record-of types mapped from XSD *simpleType*-s derived as a list type.

Description This encoding instruction designates that the record of type shall be handled as an XSD list type, namely, record of elements of instances shall be combined into a single XML list value using a single SP(32) (space) character as separator between the list elements. At decoding the XML list value shall be mapped to a TTCN-3 record of value by separating the list into its itemType elements (the whitespaces between the itemType elements shall not be part of the TTCN-3 value).

## Example

Prepared (Subject resp) ETHBAAT Jeno Balasko		No. 2/198 17-CRL 113 200/5 Uen		
Approved (Document resp) ETHLEL Elemer Lelik	Checked ETHGRY	Date 2015-05-15	Rev C	Reference

```

type record of integer Pi;
with {
    variant "list"
}

const Pi digits := {
    3, 14, 15, 9, 26
}

/* XML encoding
<S>3 14 15 9 26</S>
*/

```

## Name

Attribute syntax:      name (as ('freetext' | changeCase ) | all as changeCase ),      where changeCase := ( capitalized | uncapitalized | lowercased | uppercased )

Applicable to (TTCN-3)      Type or field of structured type. The form when *freetext* is empty shall be applied to fields of union types with the "useUnion" encoding instruction only

Description      The name encoding instruction is used when the name of the XML element or attribute differs from the name of the TTCN-3 definition or field. The name resulted from applying the name encoding attribute shall be used as the non-qualified part of the name of the corresponding XML attribute or element tag.

When the "name as '*freetext*'" form is used, *freetext* shall be used as the attribute name or element tag, instead of the name of the related TTCN-3 definition (e.g. TTCN-3 type name or field name).

The "name as " " (i.e. freetext is empty) form designates that the TTCN-3 field corresponds to an XSD unnamed type, thus its name shall not be used when encoding and decoding XML documents.

The "name as capitalized" and "name as uncapitalized" forms identify that only the first character of the related TTCN-3 type or field name shall be changed to lower case or upper case respectively.

The "name as lowercased" and "name as uppercased" forms identify that each character of the related TTCN-3 type or field name shall be changed to lower case or upper case respectively.

Prepared (Subject resp) ETHBAAT Jeno Balasko		No. 2/198 17-CRL 113 200/5 Uen		
Approved (Document resp) ETHLEL Elemer Lelik	Checked ETHGRY	Date 2015-05-15	Rev C	Reference

The "name all as capitalized", "name all as uncapitalized", "name as lowercased" and "name as uppercased" forms has effect on all direct fields of the TTCN-3 definition to which the encoding instruction is applied (e.g. in case of a structured type definition to the names of its fields in a non-recursive way but not to the name of the definition itself and not to the name of fields embedded to other fields).

### Example

```
type record S {
  charstring r,
  charstring blue,
  charstring black
}
with {
  variant (r)      "name as 'Red'";
  variant (blue)   "name as uppercased";
  variant (black)  "name as capitalized";
}

const NM outfit := { r := "shirt", blue := "trousers", black := "shoes" }
/* XML encoding
<S>
  <Red>shirt</Red>
  <BLUE>trousers</BLUE>
  <Black>shoes</Black>
</S>

*/
```

### Namespace identification

Attribute syntax: namespace as '*freetext*' [prefix '*freetext*']

Applicable to (TTCN-3) Modules; fields of record types generated for *attributes* of *complexType*s taken in to *complexType* definitions by referencing *attributeGroup*(s), defined in *schema* elements with a different (but not absent) target namespace and imported into the *schema* element which is the ancestor of the *complexType*.

### Description

The first *freetext* component identifies the namespace to be used in qualified XML attribute names and element tags at encoding, and to be expected in received XML documents. The second *freetext* component is optional and identifies the namespace prefix to be used at XML encoding. If the prefix is not specified, the encoder shall either identify the namespace as the default namespace (if all other namespaces involved in encoding the XML document have prefixes) or shall allocate a

Prepared (Subject resp) ETHBAAT Jeno Balasko		No. 2/198 17-CRL 113 200/5 Uen		
Approved (Document resp) ETHLEL Elemer Lelik	Checked ETHGRY	Date 2015-05-15	Rev C	Reference

prefix to the namespace (if more than one namespace encoding instructions are missing the prefix part).

### Example

```

type record S {
    charstring firstName,
    charstring lastName,
    charstring middleInitial
}
with { variant "namespace as 'http://www.example.org/test' prefix 'tst'" }

const S jrh := { "John", "Doe", "M" }

/* XML encoding
<tst:S xmlns:tst="http://www.example.org/test">
  <firstName>John</firstName>
  <lastName>Doe</lastName>
  <middleInitial>M</middleInitial>
</tst:S>
*/

```

### Nillable elements

Attribute syntax: useNil

Applicable to (TTCN-3) Top-level record types or record fields generated for nillable XSD *element* elements.

Description The encoding instruction designates that the encoder, when the optional field of the record (corresponding to the nillable element) is omitted, shall produce the XML element with the `xsi:nil="true"` attribute and no value. When the nillable XML element is present in the received XML document and carries the `xsi:nil="true"` attribute, the optional field of the record in the corresponding TTCN-3 value shall be omitted. If the nillable XML element carries the `xsi:nil="true"` attribute and has children (either any character or element information item) at the same time, the decoder shall initiate a test case error.

### Example

```

module UseNil {
    type record Size {
        integer sizeval optional
    }
    with { variant "useNil" }

    type record NilProduct {
        charstring name,
        ProductColor color,
        Size size
    }
}

```

Prepared (Subject resp) ETHBAAT Jenő Balasko		No. 2/198 17-CRL 113 200/5 Uen		
Approved (Document resp) ETHLEL Elemer Lelik	Checked ETHGRY	Date 2015-05-15	Rev C	Reference

```
const NilProduct absent := {
  name := "no shirt",
  color := red,
  size := { omit }
}

const NilProduct present := {
  name := "shirt",
  color := red,
  size := { 10 }
}

}
with {
  encode "XML";
  variant "controlNamespace 'http://www.w3.org/2001/XMLSchema-instance' prefix
'xsi'"
}
/* XML encoding of absent:
<Product xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance">
<name>no shirt</name>
<color>red</color>
<size xsi:nil="true"/>
</Product>

XML encoding of present:
<Product xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance">
<name>shirt</name>
<color>red</color>
<size xsi:nil="false">10</size>
</Product>

Another possible XML encoding of present:
<Product xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance">
<name>shirt</name>
<color>red</color>
<size>10</size>
</Product>
*/
```

## Text

**Attribute syntax:** text ('name' as ('freetext')) | all as changeCase), where changeCase has been defined in section 0 above.

**Applicable to (TTCN-3)** Enumeration types generated for XSD enumeration facets where the enumeration base is a string type, and the name(s) of one or more TTCN-3 enumeration values are different from the related XSD enumeration item. Also applies to XSD.Boolean types, instances of XSD.Boolean types.

**Description** When *name* is used, it shall be generated for the differing enumerated values only. The *name* shall be the identifier of the TTCN-3 enumerated value the given instruction relates to. If the difference is that the first character of the XSD enumeration item value is a capital letter while the identifier of the related TTCN-3 enumeration value starts with a

Prepared (Subject resp) ETHBAAT Jeno Balasko		No. 2/198 17-CRL 113 200/5 Uen		
Approved (Document resp) ETHLEL Elemer Lelik	Checked ETHGRY	Date 2015-05-15	Rev C	Reference

small letter, the "text '*name*' as capitalized" form shall be used. Otherwise, *freetext* shall contain the value of the related XSD enumeration item. If the first characters of all XSD enumeration items are capital letters, while the names of all related TTCN-3 enumeration values are identical to them except the case of their first characters, the "text all as capitalized" form shall be used. The encoding instruction designates that the encoder shall use *freetext* or the capitalized name(s) when encoding the TTCN-3 enumeration value(s) and vice versa. When the text encoding attribute is used with XSD.Boolean types, the decoder shall accept all four possible XSD boolean values and map the received value 1 to the TTCN-3 boolean value **true** and the received value 0 to the TTCN-3 boolean value **false**. When the text encoding attribute is used on the instances of the XSD.Boolean type, the encoder shall encode the TTCN-3 values according to the encoding attribute (i.e. **true** as 1 and **false** as 0).

#### Comment

For XSD.Boolean types, either of the forms "text 'true' as '1'" and "text 'false' as '0'" implies the other, i.e. Titan considers that both have been specified. Together, these two forms have the same effect as "text" (detailed in the last paragraph of Description).

#### Example

```
type enumerated ProductColor { red(0), light_green(1), blue(2) }
with {
  variant "text 'red' as uppercased";
  variant "text 'light_green' as 'Light Green'";
  variant "text 'blue' as capitalized"
};

type boolean Availability
with {
  variant "text"
}

type record T {
  ProductColor color,
  Availability available
}

const T prod := {
  color := light_green,
  available := true
}

/* XML encoding
<S>
  <color>Light Green</color>
  <available>1</available>
```

Prepared (Subject resp) ETHBAAT Jeno Balasko		No. 2/198 17-CRL 113 200/5 Uen		
Approved (Document resp) ETHLEL Elemer Lelik	Checked ETHGRY	Date 2015-05-15	Rev C	Reference

</S>  
\*/

## Untagged

Attribute syntax: untagged

Applicable to (TCN-3): Type; or field of a record, set, union; or the embedded type of a record-of or set-of. This encoding instruction is ignored if applied to a type which is encoded as the top-level type. It will take effect when a field of this type is encoded as a component of the enclosing structured type.

Description: The encoding instruction designates that the encoder shall omit the tag.

Example: “untagged” applied to a field.

```
type record Prod {
  charstring name,
  float price,
  charstring description
}
with {
  variant (description) "untagged"
}

const Prod prod := {
  name      := "Danish Blue",
  price     := 3.49,
  description := "Soft blue cheese"
}
/* generated XML:
<Prod>
  <name>Danish Blue</name>
  <price>3.490000</price>
  Soft blue cheese</Prod>
*/
```

Example: “untagged” applied to a type

## Use number

Attribute syntax: useNumber

Applicable to (TTCN-3) Enumeration types generated for XSD enumeration facets where the enumeration base is integer

Description The encoding instruction designates that the encoder shall use the integer values associated to the TTCN-3 enumeration values to produce the value of the corresponding XML attribute or

Prepared (Subject resp) ETHBAAT Jeno Balasko		No. 2/198 17-CRL 113 200/5 Uen		
Approved (Document resp) ETHLEL Elemer Lelik	Checked ETHGRY	Date 2015-05-15	Rev C	Reference

element (as opposed to the names of the TTCN-3 enumeration values) and the decoder shall map the integer values in the received XML attribute or element to the appropriate TTCN-3 enumeration values.

### Example

```
type enumerated ProductColor { red(0), green(1), blue(2) }
with {
    variant "useNumber"
}

type record NrProduct {
    charstring name,
    ProductColor color,
    integer size
}

const NrProduct rval := {
    name := "shirt",
    color := red,
    size := { sizeval := 10 }
}

/* XML encoding:
<NrProduct>
  <name>shirt</name>
  <color>0</color>
  <size>10</size>
</NrProduct>

*/
```

### Use order

Attribute syntax: useOrder

Applicable to (TTCN-3) Record type definition, generated for XSD *complexType*-s with *all* constructor

Description The encoding instruction designates that the encoder shall encode the values of the fields corresponding to the children elements of the *all* constructor according to the order identified by the elements of the **order** field. At decoding, the received values of the XML elements shall be placed in their corresponding record fields and a new record of element shall be inserted into the **order** field for each XML element processed (the final order of the record of elements shall reflect the order of the XML elements in the encoded XML document).

### Example

```
type record UOProduct {
    record of enumerated { id, name, price, color } order,
    integer id,
    charstring name,
```

Prepared (Subject resp) ETHBAAT Jeno Balasko		No. 2/198 17-CRL 113 200/5 Uen		
Approved (Document resp) ETHLEL Elemer Lelik	Checked ETHGRY	Date 2015-05-15	Rev C	Reference

```
        float      price,
        charstring color
    }
    with {
        variant "useOrder";
    }

    const UOProduct rval := {
        order := { id, color, price, name },
        id    := 100,
        name   := "shirt",
        price  := 12.23,
        color  := "red"
    }
    /* XML encoding:
    <UOProduct>
    <id>100</id>
    <color>red</color>
    <price>12.230000</price>
    <name>shirt</name>
    </UOProduct>

    */
```

## Use union

Attribute syntax:            useUnion

Applicable to (TTCN-3)    unions (all alternatives of the union must be character-encodable)

Description                The encoding instruction designates that the encoder shall not use the start-tag and the end-tag around the encoding of the selected alternative (field of the TTCN-3 union type).

A type identification attribute (`xsi:type`, where `xsi` is the prefix of the control namespace) can be used to identify the selected alternative, or the encoding of the alternatives must be distinct enough that the decoder can determine the selected field based solely on its value.

The decoder shall place the received XML value into the corresponding alternative of the TTCN-3 union type, based on the received value and the type identification attribute, if present.

The encoder will always use the type identification attribute to identify the selected field whenever possible.

If the union has the `attribute` or `untagged` encoding instructions, or is the component of a record of or set of with the `list` encoding

Prepared (Subject resp) ETHBAAT Jeno Balasko		No. 2/198 17-CRL 113 200/5 Uen		
Approved (Document resp) ETHLEL Elemer Lelik	Checked ETHGRY	Date 2015-05-15	Rev C	Reference

instruction, then the insertion of the type identification attribute is not possible.

#### Comment

There is no check implemented to ensure the fields are sufficiently distinct. If no type identification attribute is present, the first field (in the order of declaration) that manages to successfully decode the XML value will be the selected alternative.

#### Restrictions

The use of the XSD type `QName` or other unions with the `useType` or `useUnion` coding instructions as alternatives are not supported.

Adding the `name as ``` coding instruction to fields of the union should encode the field's XSD base type instead of its name as the type identification attribute, however this is currently not supported, and will instead encode the field without the type identification attribute.

#### Example 1

```
type union ProductId {
  integer c1,
  integer c2,
  integer c3
}
with {
  variant "useUnion"
}

const Product rval := {
  id := { c2 := 100 },
  price := 25.34,
  color := "green"
}
/*
<Product xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance">
  <id xsi:type="c2">100</id>
  <price>2.534E1</price>
  <color>green</color>
</Product>
*/
```

#### Example 2

```
type union IntStr {
  integer int,
  charstring str
}
with {
  variant "useUnion"
}

type record Data {
  IntStr atr,
  record of IntStr values
}
with {
  variant(atr) "attribute";
  variant(values) "list";
}

const Data d := {
```

Prepared (Subject resp) ETHBAAT Jeno Balasko		No. 2/198 17-CRL 113 200/5 Uen		
Approved (Document resp) ETHLEL Elemer Lelik	Checked ETHGRY	Date 2015-05-15	Rev C	Reference

```
atr := { int := 26 },
values := { { str := "abc" }, { str := "x" }, { int := -7 } }
}
/*
<Data xmlns:xsi='http://www.w3.org/2001/XMLSchema-instance' atr='26'>
  <values>abc x -7</values>
</Data>
*/
```

## Use type

Attribute syntax: useType

Applicable to (TTCN-3) unions

**Description**

The encoding instruction designates that the encoder shall not use the start-tag and the end-tag around the encoding of the selected alternative (field of the TTCN-3 union type), a type identification attribute (`xsi:type`, where `xsi` is the prefix of the control namespace) will be used to identify the selected alternative. This attribute may be omitted in the case of the first alternative.

The decoder shall place the received XML value into the corresponding alternative of the TTCN-3 union type, based on the received value and the type identification attribute. The first alternative will be selected if this attribute is not present.

The encoder will never insert the type identification attribute for the first alternative.

Any attributes the selected alternative might have will be inserted to the union's XML tag instead (after the type identification attribute, if it exists).

## Example

```
type record Shirt {
  charstring color,
  charstring make,
  integer size
}

type record Trousers {
  boolean available,
  charstring color,
  charstring make
} with {
  variant(available) "attribute"
}

type record Shoes {
  boolean available,
  string color,
  integer size
} with {
  variant(available) "attribute"
```

Prepared (Subject resp) ETHBAAT Jeno Balasko		No. 2/198 17-CRL 113 200/5 Uen		
Approved (Document resp) ETHLEL Elemer Lelik	Checked ETHGRY	Date 2015-05-15	Rev C	Reference

```

    }

    type union Product {
        Shirt shirt,
        Trousers trousers,
        Shoes shoes
    } with {
        variant "useType"
    }

    const Product pr1 := {
        shoes := {
            available := false,
            color := "red",
            size := 9
        }
    }
    /*
    <Product xmlns:xsi='http://www.w3.org/2001/XMLSchema-instance' xsi:type='shoes'
    available='false'>
        <color>red</color>
        <size>9</size>
    </Product>
    */

    const Product pr2 := {
        shirt := {
            color := "red",
            make := "ABC Company",
            size := 9
        }
    }
    /*
    <Product xmlns:xsi='http://www.w3.org/2001/XMLSchema-instance'>
        <color>red</color>
        <make>ABC Company</make>
        <size>9</size>
    </Product>
    */

```

## Whitespace control

Attribute syntax:	whitespace (preserve replace collapse)
Applicable to (TTCN-3)	String types or fields of structured types generated for XSD components with the <i>whitespace</i> facet.
Description	<p>The encoding instruction designates that the encoder shall normalize the encoded XML values corresponding to the TTCN-3 construct with the whitespace encoding instruction, and the received XML value shall be normalized before decoding as below.</p> <ul style="list-style-type: none"> <li>• preserve: no normalization shall be done, the value is not changed.</li> <li>• replace: all occurrences of HT(9) (horizontal tabulation), LF(10) (line feed) and CR(13)</li> </ul>

Prepared (Subject resp) ETHBAAT Jeno Balasko		No. 2/198 17-CRL 113 200/5 Uen		
Approved (Document resp) ETHLEL Elemer Lelik	Checked ETHGRY	Date 2015-05-15	Rev C	Reference

(carriage return) shall be replaced with an SP(32) (space) character.

- collapse: after the processing implied by replace, contiguous sequences of SP(32) (space) characters are collapsed to a single SP(32) (space) character, and leading and trailing SP(32) (space) characters are removed.

#### Example 1

```
type charstring R
with {
    variant "whiteSpace replace"
}
const R rval := "First Line Second Line";
/* The following is a possible XML encoding of 'rval'. During decoding it will
be normalized to the value of 'rval'.
<R>First
Line
Second
Line</R>
*/
```

#### Example 2

```
type charstring C
with {
    variant "whiteSpace collapse"
}
const C cval := "First Line Second Line";
/* The following is a possible XML encoding of 'cval'. During decoding it will
be normalized to the value of 'cval'.
<C>
    First Line
    Second Line
</C>
*/
```

## 4.26 JSON Encoder and Decoder

The JSON encoder and decoder handles JSON-based protocols. The encoder converts abstract TTCN-3 structures (or types) into a JSON representation (see RFC 7159). The decoder converts JSON data into values of abstract TTCN-3 structures.

This section covers the coding rules in general, the attributes controlling them and the encoder / decoder external functions.

### 4.26.1 General rules and restrictions

You can use the encoding rules defined in this section to encode and decode the following TTCN-3 types:

- anytype
- array
- bitstring
- boolean
- charstring

Prepared (Subject resp) ETHBAAT Jeno Balasko		No. 2/198 17-CRL 113 200/5 Uen		
Approved (Document resp) ETHLEL Elemer Lelik	Checked ETHGRY	Date 2015-05-15	Rev C	Reference

- enumerated
- float
- hexstring
- integer
- objid
- octetstring
- record, set
- record of, set of
- union
- universal charstring
- verdicttype

The rules also apply to the following ASN.1 types (if imported to a TTCN-3 module):

- ANY
- BIT STRING
- BOOLEAN
- BMPString
- CHOICE, open type (in instances of parameterized types)
- ENUMERATED
- GeneralString
- GraphicString
- IA5String
- INTEGER
- NULL
- NumericString
- OBJECT IDENTIFIER
- OCTET STRING
- PrintableString
- RELATIVE-OID
- SEQUENCE, SET
- SEQUENCE OF, SET OF
- TeletexString
- UniversalString
- UTF8String
- VideotexString
- VisibleString

JSON encoding and decoding is allowed for types with the attribute 'encode "JSON"' and for types with at least one JSON variant attribute (see 4.26.2). The basic types specified in the list above support JSON encoding and decoding by default. In case of records, sets, unions and ASN.1 open types every field must also support JSON coding. In case of array, record of and set of structures the element type must also support JSON coding.

The attribute 'encode "JSON"' can also be set globally (at module level), allowing JSON coding for all types defined in that module.

Prepared (Subject resp) ETHBAAT Jenő Balasko		No. 2/198 17-CRL 113 200/5 Uen		
Approved (Document resp) ETHLEL Elemer Lelik	Checked ETHGRY	Date 2015-05-15	Rev C	Reference

Types imported from ASN.1 modules (from the list above) automatically have JSON coding allowed and cannot have JSON variant attributes.

#### 4.26.1.1 Basic types

The basic TTCN-3 types are encoded as JSON values.

All integer values and most float values are encoded as JSON numbers. The special float values “infinity”, “-infinity” and “not\_a\_number” are encoded as JSON strings.

Boolean values are encoded with the JSON literals “true” and “false”.

Bitstring, hexstring and octetstring values (and values of the ASN.1 ANY type) appear as JSON strings containing the bits or hex digits as characters.

Charstrings, universal charstrings and values of ASN.1 string types are encoded as JSON strings. Charstrings appear exactly like in TTCN-3. Universal charstrings will appear in UTF-8 encoding. JSON strings may contain the escaped character \u followed by 4 hex digit characters, the decoder will convert this into the character represented by the hex digits.

Object identifiers are encoded as JSON strings containing the components (in number form) separated by dots.

Verdicttype and enumerated types are encoded as JSON strings. The string contains the name of the verdict type or enumerated value.

The ASN.1 NULL value is encoded with the JSON literal “null”.

Note: the JSON decoder ignores all type restrictions and will successfully decode values that contradict them (e.g.: a record of/set of type with the length (3..5) restriction will successfully decode an array of 8 elements), with the exception of arrays. The restrictions of ASN.1 string types are ignored as well (e.g.: NumericStrings can decode strings containing letters).

#### 4.26.1.2 Structured types

Array, record of and set of structures are encoded as JSON arrays. Their elements will appear in the order they appear in TITAN.

Records and sets are encoded as JSON objects. The JSON object will contain the field name and value pairs of each field in the order they are declared in. Omitted optional fields will be skipped.

The decoder will accept the record / set field name and value pairs in any order, but every non-optional field must be present. Optional fields that do not appear in the JSON object will be omitted.

Prepared (Subject resp) ETHBAAT Jeno Balasko		No. 2/198 17-CRL 113 200/5 Uen		
Approved (Document resp) ETHLEL Elemer Lelik	Checked ETHGRY	Date 2015-05-15	Rev C	Reference

Unions, anytypes and ASN.1 open types are encoded as JSON objects. The object will contain one name-value pair: the name of the selected field and its value.

#### 4.26.2 Attributes

The following sections describe the TTCN-3 attributes that influence JSON coding (only affects TTCN-3 types, ASN.1 types cannot have attributes that influence JSON coding).

All JSON attributes begin with the word 'JSON' followed by a colon ("JSON:<attribute>"). Any number of white spaces (spaces and tabs only) can be added between each word or identifier in the attribute syntax, but at least one is necessary if the syntax does not specify a separator (a comma or a colon).

Example:

```
...
variant(field1) "JSON:omit as null";           // ok
variant(field2) "JSON : omit as null";         // ok (extra spaces)
variant(field3) "JSON      :      omit      as      null"; // ok (with tabs)
variant(field4) "JSON:omit as null";           // not ok
```

##### Omit as null

Attribute syntax      omit as null

Applicable to (TTCN-3)      Optional fields of records and sets

Description      If set, the value of the specified optional field will be encoded with the JSON literal 'null' if the value is omitted. By default omitted fields (both their name and value) are skipped entirely. The decoder ignores this attribute and accepts both versions.

Example:

```
type record PhoneNumber {
  integer countryPrefix optional,
  integer networkPrefix,
  integer localNumber
} with {
  variant(countryPrefix) "JSON:omit as null"
}

var PhoneNumber pn := { omit, 20, 1234567 }

// JSON code with the attribute:
// {"countryPrefix":null,"networkPrefix":20, "localNumber":1234567}
// JSON code without the attribute:
// {"networkPrefix":20, "localNumber":1234567}
```

Prepared (Subject resp) ETHBAAT Jenö Balasko		No. 2/198 17-CRL 113 200/5 Uen		
Approved (Document resp) ETHLEL Elemer Lelik	Checked ETHGRY	Date 2015-05-15	Rev C	Reference

### Name as ...

Attribute syntax      name as <alias>

Applicable to (TTCN-3)      Fields of records, sets and unions

Description      Gives the specified field a different name in the JSON code. The encoder will use this alias instead of the field's name in TTCN-3, and the decoder will look for this alias when decoding this field. The syntax of the alias is the same as the syntax of an identifier in TITAN (regex: [A-Za-z][A-Za-z0-9\_]\*).

### Example:

```
type union PersionID {
    integer numericID,
    charstring email,
    charstring name
} with {
    variant(numericID) "JSON:name as ID";
    variant(email) "JSON:name as Email";
    variant(name) "JSON:name as Name";
}

type record of PersionID PersionIDs;

var persionIDs pids := { { numericID := 189249214 }, { email := "jdoe@mail.com" }, { name := "John Doe" } };

// JSON code:
// [{"ID":189249214},{"Email":"jdoe@mail.com"}, {"Name":"John Doe"}]
```

### As value

Attribute syntax      as value

Applicable to (TTCN-3)      Unions

Description      The union will be encoded as a JSON value instead of as a JSON object with one name-value pair (the name of the selected field and the surrounding braces will be omitted). This allows the creation of heterogenous arrays in the JSON document (e.g. ["text",10,true,null]).

Since the field name no longer appears in the JSON document, the decoder will determine the selected field based on the type of the value. The first field (in the order of declaration) that can successfully decode the value will be the selected one.

Note      Pay close attention to the order of the fields when using this attribute. It's a good idea to declare more

Prepared (Subject resp) ETHBAAT Jenő Balasko		No. 2/198 17-CRL 113 200/5 Uen		
Approved (Document resp) ETHLEL Elemer Lelik	Checked ETHGRY	Date 2015-05-15	Rev C	Reference

restrictive fields before less restrictive ones (e.g.: hexstring is more restrictive than universal charstring, because hexstring can only decode hex digits, whereas universal charstring can decode any character; see also examples below).

### Example:

```

type union U1 { // good order of fields
    integer i,
    float f,
    octetstring os,
    charstring cs
} with {
    variant "JSON : as value"
}

type union U2 { // bad order of fields
    float f,
    integer i,
    charstring cs,
    octetstring os
} with {
    variant "JSON : as value"
}

type record of U1 RoU1;
type record of U2 RoU2;

var RoU1 v_rou1 := { { i := 10 }, { f := 6.4 }, { os := '1ED5'O }, { cs :=
"hello" } };
var RoU2 v_rou2 := { { i := 10 }, { f := 6.4 }, { os := '1ED5'O }, { cs :=
"hello" } };

// Both v_rou1 and v_rou2 will be encoded into:
// [10,6.4,"1ED5","hello"]
// This JSON document will be decoded into v_rou1, when decoding as type RoU1,
// however it will not be decoded into v_rou2, when decoding as RoU2, instead
// the float field will decode both numbers and the charstring field will
// decode both strings: { { f := 10.0 }, { f := 6.4 }, { cs := "1ED5" },
// { cs := "hello" } };

```

### Default

Attribute syntax	default(<value>)
Applicable to (TTCN-3)	Fields (basic types only) of records and sets
Description	<p>The decoder will set the given value to the field if it does not appear in the JSON document.</p> <p>The &lt;value&gt; can contain the JSON encoding of a value of the field's type. String types don't need the starting and ending quotes. All JSON escaped characters can be used, plus the \) escape which will be considered a ')' (right round bracket) character.</p> <p>Optional fields with a default value will be set to <code>omit</code> if the field is set to <code>null</code> in JSON code, and</p>

Prepared (Subject resp) ETHBAAT Jeno Balasko		No. 2/198 17-CRL 113 200/5 Uen		
Approved (Document resp) ETHLEL Elemer Lelik	Checked ETHGRY	Date 2015-05-15	Rev C	Reference

will use the default value if the field does not appear in the JSON document.

Example:

```
type record Product {
  charstring name,
  float price,
  octetstring id optional,
  charstring from
} with {
  variant(id) "JSON : default (FFFF)"
  variant(from) "JSON:default(Hungary)"
}

// { "name" : "Shoe", "price" : 29.50 } will be decoded into:
// { name := "Shoe", price := 29.5, id := 'FFFF'O, from := "Hungary" }

// { "name" : "Shirt", "price" : 12.99, "id" : null } will be decoded into:
// { name := "Shirt", price := 12.99, id := omit, from := "Hungary" }
```

### 4.26.3 External functions

JSON encoder / decoder functions must have the “encode (JSON)” / “decode (JSON)” attribute set.

Faults in the JSON encoding/decoding process produce errors by default, but this can be modified with the `errorbehavior` attribute. ([Codec error handling](#))

JSON encoder functions can also have the “printing(compact)” or “printing(pretty)” attributes. This specifies whether the encoder should add extra white spaces to the JSON code or not. This attribute cannot be set at module level.

If compact printing is selected (or if the printing attribute is not set) no white spaces are added to the JSON code, making it as short as possible.

Pretty printing makes the code easier to read by adding spaces, new lines and indenting.

Example:

```
type enumerated Day { Monday, Tuesday, Wednesday, Thursday, Friday, Saturday,
Sunday };

type record Date {
  charstring month,
  integer dayIdx,
  Day dayName
}

type record of Date Dates;

type record PhoneNumber {
  integer countryPrefix optional,
```

Prepared (Subject resp) ETHBAAT Jeno Balasko		No. 2/198 17-CRL 113 200/5 Uen		
Approved (Document resp) ETHLEL Elemer Lelik	Checked ETHGRY	Date 2015-05-15	Rev C	Reference

```

        integer networkPrefix,
        integer localNumber
    } with {
        variant(countryPrefix) "JSON:omit as null"
    }

type record Profile {
    charstring name,
    PhoneNumber phoneNo,
    charstring emailAddr,
    Dates meetings
} with {
    variant(phoneNo) "JSON: name as phone";
    variant(emailAddr) "JSON: name as email";
}

external function f_enc_profile(in Profile par) return octetstring
    with { extension "prototype(convert) encode(JSON) printing(pretty)" }

...

var Profile prof := { "John Doe", { omit, 20, 1234567 }, "jdoe@mail.com", { {
    "December", 31, Saturday }, { "February", 7, Friday } } };

log(f_enc_profile(prof));

// JSON code:
// {
//     "name" : "John Doe",
//     "phone" : {
//         "countryPrefix" : null,
//         "networkPrefix" : 20,
//         "localNumber" : 1234567
//     },
//     "email" : "jdoe@mail.com",
//     "meetings" : [
//         {
//             "month" : "December",
//             "dayIdx" : 31,
//             "dayName" : "Saturday"
//         },
//         {
//             "month" : "February",
//             "dayIdx" : 7,
//             "dayName" : "Friday"
//         }
//     ]
// }

```

#### 4.26.4 Converting TTCN-3 and ASN.1 types to a JSON schema

The TITAN compiler can convert type definitions in TTCN-3 and ASN.1 modules into a JSON schema that validates the JSON encoding of these types.

Note: the names of ASN.1 modules, types and fields will appear in TTCN-3 form (as if they were imported into a TTCN-3 module). E.g.: the ASN.1 names `Protocol-Elem` and `value` will appear as `Protocol_Elem` and `value_` respectively.

Prepared (Subject resp) ETHBAAT Jenő Balasko		No. 2/198 17-CRL 113 200/5 Uen		
Approved (Document resp) ETHLEL Elemer Lelik	Checked ETHGRY	Date 2015-05-15	Rev C	Reference

#### 4.26.4.1 Usage

The compiler option `--ttn2json` shall be used for the conversion, followed by JSON schema generator specific options and the list of TTCN-3 and ASN.1 file names.

The option `-j` restricts the TTCN-3 types used in the conversion: only those that have JSON coding enabled will be converted. By default all TTCN-3 types that can be converted will be used. This option does not affect ASN.1 types, these will always be converted.

If option `-f` is set, then the schema will only validate types that have JSON encoding and/or decoding functions, otherwise all types it will validate all types included in the schema.

The options `-A` and `-T` can be used before each input file to specify its type (`-A` for ASN.1 files and `-T` for TTCN-3 files). If a file is not preceded by either of these option, then the compiler will attempt to determine its type based on its contents.

The last parameter specifies the name of the JSON schema file if it is preceded by a dash (-). Otherwise the name of the schema will be created using the first input file name (its `.asn` or `.ttn` extension will be replaced by `.json`, or, if it doesn't have either of these extension, then `.json` will simply be appended to its end).

##### Usage examples:

```
compiler --ttn2json -T module1.ttn -A module2.asn - schema.json
compiler --ttn2json -j module1.ttn module2.asn
```

The first example will generate the `schema.json` JSON document containing the schema, the second one will generate `module1.json` (and only JSON-encodable types will be included). These document will have the “pretty” printing format mentioned in 4.26.3.

#### 4.26.4.2 Top level

On the top level the schema contains a JSON object with 2 properties.

The first property, “definitions”, has the schema segments of the type definitions in the TTCN-3 and ASN.1 modules as its value. This value is a JSON object with one property (key-value pair) for each module. Each property has the module name as its key and an object containing the schema segments for the types defined in that module as its key. Similarly, each type definition’s key is the type name and its value is the type’s schema segment (these will be described in the next sections).

Prepared (Subject resp) ETHBAAT Jeno Balasko		No. 2/198 17-CRL 113 200/5 Uen		
Approved (Document resp) ETHLEL Elemer Lelik	Checked ETHGRY	Date 2015-05-15	Rev C	Reference

The second top level property is an “anyOf” structure, which contains references to the TTCN-3 and ASN.1 types’ schema segments under “definitions”. The types listed here are the ones validated by the schema. If the compiler option `-f` is set, then only the schema segments of types that have either a JSON encoding or decoding function (or both) will be referenced (ASN.1 types can have JSON encoding/decoding functions declared in TTCN-3 modules that import them). Extra information related to the encoding/decoding function(s) is stored after each reference.

### Example:

```
module MyModule {

    type enumerated Height { Short, Medium, Tall };

    type set Num {
        integer num
    }

    external function f_enc_h(in Height h) return octetstring
        with { extension "prototype(convert) encode(JSON)" }

    external function f_dec_n(in octetstring o) return Num
        with { extension "prototype(convert) decode(JSON)" }

} with {
    encode "JSON"
}
```

Prepared (Subject resp) ETHBAAT Jeno Balasko		No. 2/198 17-CRL 113 200/5 Uen		
Approved (Document resp) ETHLEL Elemer Lelik	Checked ETHGRY	Date 2015-05-15	Rev C	Reference

```
// Generated JSON schema:
// {
//   "definitions" : {
//     "MyModule" : {
//       "Height" : {
//         "enum" : [
//           "Short",
//           "Medium",
//           "Tall"
//         ],
//         "numericValues" : [
//           0,
//           1,
//           2
//         ]
//       },
//       "Num" : {
//         "type" : "object",
//         "subType" : "set",
//         "properties" : {
//           "num" : {
//             "type" : "integer"
//           }
//         },
//         "additionalProperties" : false,
//         "required" : [
//           "num"
//         ]
//       }
//     },
//     "anyOf" : [
//       {
//         "$ref" : "#/definitions/MyModule/Height",
//         "encoding" : {
//           "prototype" : [
//             "convert",
//             "f_enc_h",
//             "h"
//           ]
//         }
//       },
//       {
//         "$ref" : "#/definitions/MyModule/Num",
//         "decoding" : {
//           "prototype" : [
//             "convert",
//             "f_dec_n",
//             "o"
//           ]
//         }
//       }
//     ]
//   }
// }
```

#### 4.26.4.3 Rules and extra keywords

The JSON schema will be generated according to the rules of the IETF draft v4 (see <http://json-schema.org/documentation.html>).

Prepared (Subject resp) ETHBAAT Jeno Balasko		No. 2/198 17-CRL 113 200/5 Uen		
Approved (Document resp) ETHLEL Elemer Lelik	Checked ETHGRY	Date 2015-05-15	Rev C	Reference

In addition to the “definitions” keyword specified above, the schema segments of the type definitions can use the following extra keywords:

- “subType”: distinguishes 2 or more types from each other, that otherwise have no other differences in their schema segments (such as: charstring and universal charstring; record and set; record of and set of)
- “fieldOrder”: stores the order of the fields of a record or set (value: an array containing the field names) – only needed if there are at least 2 fields
- “originalName”: stores the original name of a record/set field (see section 4.26.4.8)
- “unusedAlias”: stores the alias of a record/set/union field name, if it doesn’t appear under a “properties” keyword (see section 4.26.4.8)
- “omitAsNull”: specifies if the “omit as null” JSON encoding instruction is present for an optional field of a record or set (see sections 4.26.4.5 and 4.26.4.8)
- “numericValues”: lists the numeric values of the enumerated items (in the same order as the items themselves)

A schema segment is generated for each type that has its own definition in TTCN-3. References to other types in TTCN-3 type definitions are converted into references in the JSON schema. Schema segments for embedded TTCN-3 type definitions are defined inside their parent type’s schema segment (see sections 4.26.4.5 and 4.26.4.6 for examples).

The examples in the following sections will only contain JSON schema segments, not complete schemas (generated for one or more TTCN-3/ASN.1 type definitions, not the whole module). These schema segments contain the type name and the schema that validates the type. In a complete JSON schema these segments would be directly under the module’s property, which is under “definitions” (for examples see section 4.26.4.2, types “Height” and “Num”).

#### 4.26.4.4 Schema segments for basic types

The JSON encoding of basic types is detailed in section 4.26.1.1. Here are their schema segments:

```
// integer(TTCN-3) and INTEGER(ANS.1):  
// {  
//   "type" : "integer"  
// }
```

Prepared (Subject resp) ETHBAAT Jeno Balasko		No. 2/198 17-CRL 113 200/5 Uen		
Approved (Document resp) ETHLEL Elemer Lelik	Checked ETHGRY	Date 2015-05-15	Rev C	Reference

```
// float(TTCN-3) and REAL(ASN.1):
// {
//     "anyOf" : [
//         {
//             "type" : "number"
//         },
//         {
//             "enum" : [
//                 "not_a_number",
//                 "infinity",
//                 "-infinity"
//             ]
//         }
//     ]
// }

// boolean(TTCN-3) and BOOLEAN(ASN.1):
// {
//     "type" : "boolean"
// }

// charstring(TTCN-3), NumericString(ASN.1), PrintableString(ASN.1),
// IA5String(ASN.1) and VisibleString(ASN.1):
// {
//     "type" : "string",
//     "subType" : "charstring"
// }

// universal charstring(TTCN-3), GeneralString(ASN.1), UTF8String(ASN.1),
// UniversalString(ASN.1), BMPString(ASN.1), GraphicString(ASN.1),
// TeletexString(ASN.1) and VideotexString(ASN.1):
// {
//     "type" : "string",
//     "subType" : "universal charstring"
// }

// bitstring(TTCN-3) and BIT STRING(ASN.1):
// {
//     "type" : "string",
//     "subType" : "bitstring",
//     "pattern" : "^[01]*$"
// }

// hexstring(TTCN-3):
// {
//     "type" : "string",
//     "subType" : "hexstring",
//     "pattern" : "^[0-9A-Fa-f]*$"
// }

// octetstring(TTCN-3), OCTET STRING(ASN.1) and ANY(ASN.1):
// {
//     "type" : "string",
//     "subType" : "octetstring",
//     "pattern" : "^[0-9A-Fa-f][0-9A-Fa-f]*$"
// }

// NULL(ASN.1):
// {
//     "type" : "null"
// }

// objid(TTCN-3), OBJECT IDENTIFIER(ASN.1) and RELATIVE-OID(ASN.1):
// {
//     "type" : "string",
//     "subType" : "objid",
//     "pattern" : "^[0-2][.][1-3]?[0-9]([.][0-9]|([1-9][0-9]+))*$"
// }
```

Prepared (Subject resp) ETHBAAT Jeno Balasko		No. 2/198 17-CRL 113 200/5 Uen		
Approved (Document resp) ETHLEL Elemer Lelik	Checked ETHGRY	Date 2015-05-15	Rev C	Reference

```
// verdicttype:
// {
//     "enum" : [
//         "none",
//         "pass",
//         "inconc",
//         "fail",
//         "error"
//     ]
// }

// Enumerated types are converted the same way as the verdicttype with the
// addition of the numeric values. Example:
// TTCN-3:
type enumerated Season {
    spring (1), summer (2), fall (3), winter (4)
}
// ASN.1:
Season ::= ENUMERATED {
    spring (1), summer (2), fall (3), winter (4)
}

// JSON schema segment for type "Season":
// "Season" : {
//     "enum" : [
//         "spring",
//         "summer",
//         "fall",
//         "winter"
//     ],
//     "numericValues" : [
//         1,
//         2,
//         3,
//         4
//     ]
// }
```

#### 4.26.4.5 Schema segments for records and sets

The JSON object type is used for records and sets. The “properties” keyword specifies the fields of the record (each property’s key is the field name, and the value is the field’s schema segment). Additional properties are not accepted (“additionalProperties” : false). The “required” keyword determines which fields are mandatory (the names of all non-optional fields are listed here).

Optional fields have an “anyOf” structure directly under “properties” (instead of the field’s schema segment). The “anyOf” structure contains the JSON null value and the field’s schema segment. The “omitAsNull” keyword is used to specify how omitted optional values are encoded (after the “anyOf” structure).

Examples:

//     "numBarrels",
//     "barrelType"
//   ]
// }
```

#### 4.26.4.6 Schema segments for records of, sets of and arrays

The JSON array type is used for records of, sets of and arrays. The “items” keyword specifies the schema segment of the items. In case of arrays, the “minItems” and “maxItems” properties are set to the array length.

Prepared (Subject resp) ETHBAAT Jeno Balasko		No. 2/198 17-CRL 113 200/5 Uen		
Approved (Document resp) ETHLEL Elemer Lelik	Checked ETHGRY	Date 2015-05-15	Rev C	Reference

Arrays are distinguishable from records of and sets of by the “minItems” and “maxItems” keywords, so there is no need for them to have the “subType” property.

### Examples:

```
// Example 1:
// TTCN-3:
type record of bitstring Bits;
// ASN.1:
Bits ::= SEQUENCE OF BIT STRING

// Schema segment for type "Bits":
// "Bits" : {
//   "type" : "array",
//   "subType" : "record of",
//   "items" : {
//     "type" : "string",
//     "subType" : "bitstring",
//     "pattern" : "^[01]*$"
//   }
// }

// Example 2 (TTCN-3 only):
type integer Ints[4];

// Schema segment for type "Ints":
// "Ints" : {
//   "type" : "array",
//   "minItems" : 4,
//   "maxItems" : 4,
//   "items" : {
//     "type" : "integer"
//   }
// }

// Example 3:
// reference to record type Num defined in section 4.26.4.2.
// TTCN-3:
type set of Num Nums;
// ASN.1:
Nums ::= SET OF Num

// JSON schema segment for type "Nums":
// "Nums" : {
//   "type" : "array",
//   "subType" : "set of",
//   "items" : {
//     "$ref" : "#/definitions/MyModule/Num"
//   }
// }

// Example 4:
// the same thing with Num as an embedded type
// TTCN-3:
type set of set { integer num } Nums;
// ASN.1:
Nums ::= SET OF SET { num INTEGER }
```

Prepared (Subject resp) ETHBAAT Jeno Balasko		No. 2/198 17-CRL 113 200/5 Uen		
Approved (Document resp) ETHLEL Elemer Lelik	Checked ETHGRY	Date 2015-05-15	Rev C	Reference

```
// JSON schema segment for type "Nums":
// "Nums" : {
//   "type" : "array",
//   "subType" : "set of",
//   "items" : {
//     "type" : "object",
//     "subType" : "set",
//     "properties" : {
//       "num" : {
//         "type" : "integer"
//       }
//     },
//     "additionalProperties" : false,
//     "required" : [
//       "num"
//     ]
//   }
// }
```

#### 4.26.4.7 Schema segments for unions, anytype, selection type and open type

The “anyOf” structure is used for unions, open types and the anytype (if they have at least 2 fields). Each item in the “anyOf” structure represents one field of the union; they are each a JSON object with one key-value pair (one property). Same as with records, the “additionalProperties” keyword is set to false, and the one property is marked as required.

##### Examples:

```
// Example 1: union
// TTCN-3:
type union Thing {
  boolean b,
  integer i,
  charstring cs,
  record { integer num } rec
}
// ASN.1:
Thing ::= CHOICE {
  b BOOLEAN,
  i INTEGER,
  cs VisibleString,
  rec SEQUENCE { num INTEGER }
}
```

Prepared (Subject resp) ETHBAAT Jeno Balasko		No. 2/198 17-CRL 113 200/5 Uen		
Approved (Document resp) ETHLEL Elemer Lelik	Checked ETHGRY	Date 2015-05-15	Rev C	Reference

```
// Schema segment for type "Thing":
// "Thing" : {
//   "anyOf" : [
//     {
//       "type" : "object",
//       "properties" : {
//         "b" : {
//           "type" : "boolean"
//         }
//       },
//       "additionalProperties" : false,
//       "required" : [
//         "b"
//       ]
//     },
//     {
//       "type" : "object",
//       "properties" : {
//         "i" : {
//           "type" : "integer"
//         }
//       },
//       "additionalProperties" : false,
//       "required" : [
//         "i"
//       ]
//     },
//     {
//       "type" : "object",
//       "properties" : {
//         "cs" : {
//           "type" : "string",
//           "subType" : "charstring"
//         }
//       },
//       "additionalProperties" : false,
//       "required" : [
//         "cs"
//       ]
//     },
//     {
//       "type" : "object",
//       "properties" : {
//         "rec" : {
//           "type" : "object",
//           "subType" : "record",
//           "properties" : {
//             "num" : {
//               "type" : "integer"
//             }
//           },
//           "additionalProperties" : false,
//           "required" : [
//             "num"
//           ]
//         }
//       },
//       "additionalProperties" : false,
//       "required" : [
//         "rec"
//       ]
//     }
//   ]
// }
```

Prepared (Subject resp) ETHBAAT Jenö Balasko		No. 2/198 17-CRL 113 200/5 Uen		
Approved (Document resp) ETHLEL Elemer Lelik	Checked ETHGRY	Date 2015-05-15	Rev C	Reference

```
// Example 2: anytype (TTCN-3 only)
module ... {
  ...
} with {
  extension "anytype integer,charstring"
  // the anytype must be referenced at least one,
  // otherwise its schema segment won't be generated
}

// JSON schema segment for the anytype:
// "anytype" : {
//   "anyOf" : [
//     {
//       "type" : "object",
//       "properties" : {
//         "integer" : {
//           "type" : "integer"
//         }
//       },
//       "additionalProperties" : false,
//       "required" : [
//         "integer"
//       ]
//     },
//     {
//       "type" : "object",
//       "properties" : {
//         "charstring" : {
//           "type" : "string",
//           "subType" : "charstring"
//         }
//       },
//       "additionalProperties" : false,
//       "required" : [
//         "charstring"
//       ]
//     }
//   ]
// }
// }
```

The ASN.1 selection type generates the same schema segment as the specified alternative of the CHOICE would.

#### Example:

```
// Continuing example 1 (ASN.1 only):
NumRec ::= rec < Thing

// JSON schema segment for type NumRec:
// "NumRec" : {
//   "type" : "object",
//   "subType" : "record",
//   "properties" : {
//     "num" : {
//       "type" : "integer"
//     }
//   },
//   "additionalProperties" : false,
//   "required" : [
//     "num"
//   ]
// }
```

Prepared (Subject resp) ETHBAAT Jeno Balasko		No. 2/198 17-CRL 113 200/5 Uen		
Approved (Document resp) ETHLEL Elemer Lelik	Checked ETHGRY	Date 2015-05-15	Rev C	Reference

#### 4.26.4.8 Effect of coding instructions on the schema

For the list of JSON coding instructions see section 4.26.2. As mentioned before, only TTCN-3 types can have coding instructions, ASN.1 types can't.

- *omit as null* – its presence is indicated by the “omitAsNull” keyword (true, if it's present)

- *name as ...* - the alias is used under “properties” instead of the field's name in TTCN-3; the original name is stored under the “originalName” key

- *as value* – the union's “anyOf” structure contains the fields' schema segments instead of the JSON objects with one property; the field's name is stored under the “originalName” key

- *default* – specified by the “default” keyword

- *as value + name as ...* - the field name aliases are stored under the “unusedAlias” keyword, as there are no more JSON objects with one property to store them in (they are also ignored by both the schema and the encoder/decoder, and a compiler warning is displayed in this case)

Examples:

```
// Example 1: omit as null

type record Rec {
  integer num optional,
  universal charstring str optional
} with {
  variant(num) "JSON : omit as null"
}
```

Prepared (Subject resp) ETHBAAT Jeno Balasko		No. 2/198 17-CRL 113 200/5 Uen		
Approved (Document resp) ETHLEL Elemer Lelik	Checked ETHGRY	Date 2015-05-15	Rev C	Reference

```
// Schema segment for type "Rec":
// "Rec" : {
//   "type" : "object",
//   "subType" : "record",
//   "properties" : {
//     "num" : {
//       "anyOf" : [
//         {
//           "type" : "null"
//         },
//         {
//           "type" : "integer"
//         }
//       ],
//       "omitAsNull" : true
//     },
//     "str" : {
//       "anyOf" : [
//         {
//           "type" : "null"
//         },
//         {
//           "type" : "string",
//           "subType" : "universal charstring"
//         }
//       ],
//       "omitAsNull" : false
//     }
//   },
//   "additionalProperties" : false,
//   "fieldOrder" : [
//     "num",
//     "str"
//   ]
// }
```

// Example 2: name as ...

```
type set Num {
  integer num
} with {
  variant(num) "JSON : name as number"
}
```

```
// Schema segment for type "Num":
// "Num" : {
//   "type" : "object",
//   "subType" : "set",
//   "properties" : {
//     "number" : {
//       "originalName" : "num",
//       "type" : "integer"
//     }
//   },
//   "additionalProperties" : false,
//   "required" : [
//     "number"
//   ]
// }
```

// Example 3: as value and name as ...

```
// JSON schema segment for type "Rec":
// "Rec" : {
//   "type" : "object",
//   "subType" : "record",
//   "properties" : {
//     "num" : {
//       "type" : "integer",
//       "default" : 0
//     },
//     "str" : {
//       "type" : "string",
//       "subType" : "universal charstring",
//       "default" : "empty"
//     }
//   },
//   "additionalProperties" : false,
//   "fieldOrder" : [
//     "num",
//     "str"
//   ],
//   "required" : [
//     "num",
//     "str"
//   ]
// }
```

#### 4.26.4.9 External function properties in the schema

JSON encoding/decoding functions can only be declared in TTCN-3 modules, however they can be defined for both TTCN-3 types and imported ASN.1 types.

Information related to a type's JSON encoding/decoding external function is stored after the reference to the type's schema segment in the top level "anyOf" structure.

Extra JSON schema keywords for the external function properties:

- "encoding" and "decoding": stores the specifics of the encoding or decoding function as properties (directly under the top level "anyOf", after the reference to the type's schema segment)
- "prototype": an array containing the prototype of the encoding function (as a string), the function name, and the parameter names used in its declaration (directly under "encoding" or "decoding")
- "printing": stores the printing settings (values: "compact" or "pretty"; directly under "encoding")
- "errorBehavior": an object containing the error behavior modifications as its properties, each modification has the error type as key and the error handling as value (directly under "encoding" or "decoding")

Example:

Prepared (Subject resp)		No.		
ETHBAAT Jeno Balasko		2/198 17-CRL 113 200/5 Uen		
Approved (Document resp)	Checked	Date	Rev	Reference
ETHLEL Elemer Lelik	ETHGRY	2015-05-15	C	

```
module Mod {
  type record Rec {
    integer num,
    boolean b
  }

  external function f_enc(in Rec x) return octetstring with {
    extension "prototype(convert) encode(JSON) printing(pretty)"
  }

  external function f_dec(in octetstring o, out Rec x) with {
    extension "prototype(fast) decode(JSON)"
    extension "errorbehavior(ALL:WARNING, INVAL_MSG:ERROR)"
  }

} with {
  encode "JSON"
}
```

//         }
//       }
//     }
//   ]
// }
```

## 4.27 Build Consistency Checks

Executable test suites are typically put together from many sources, some of which (test ports, function libraries, etc.) are not written by the test writers themselves, but are developed independently. Sometimes, a test suite requires an external component with a certain feature or bug fix, or a certain minimum TITAN version. Building with a component which does not meet a requirement, or an old TITAN version, typically results in malfunction during execution or cryptic error messages during build. If version dependencies are specified explicitly, they can be checked during build and the mismatches can be reported.

Prepared (Subject resp) ETHBAAT Jenő Balasko		No. 2/198 17-CRL 113 200/5 Uen		
Approved (Document resp) ETHLEL Elemer Lelik	Checked ETHGRY	Date 2015-05-15	Rev C	Reference

#### 4.27.1 Version Information in TTCN-3 Files

TITAN allows test writers to specify that a certain TTCN-3 module requires a minimum version of another TTCN-3 module or a minimum version of TITAN.

##### 4.27.1.1 Format of Version Information

The format of the version information follows the format of Product Identity (Ericsson standard version information [\[19\]](#)); a combination of letters and digits according to the template `productNumber/suffix RmXnn`, where

- Product number identifies the product. It is 3 characters representing the ABC class, 3 digits called the type number and 2 to 4 digits called the sequence number. This part is optional for backward compatibility reasons.
- Suffix indicates new major versions, which are not backward compatible with previous versions (“Revision suffix”). This part is optional for backward compatibility reasons.
- R is the literal character ‘R’
- m is a single digit (“Revision digit”). It changes when the product (module) functionality is extended with new features (switching to this version is possible, but switching back might not be).
- X is an uppercase letter of the English alphabet (between A and Z inclusive) which changes when the product (module) realization changes (“Revision letter”). The following letters are not allowed: IOPQRW. Versions of a product where only this letter changes can be switched without side effect.
- nn (optional) is a two-digit number (“Verification step”) which specifies a prerelease, a version made available during development.

If the final digits are not present, the version is considered a full release, which is a higher version than any prerelease.

Example accepted formats: CRL 113 200/1 R9A; CRL 113 200 R9A; R9A  
Please note, that only these are supported from the Ericsson Naming Scheme.

Here is a possible progression of release numbers, in strictly ascending order:

R1A01, R1A02..., R1A (first full release), R1B01, R1B02..., R1B, R1C, R2A, R2B01, R2B02..., R2B, R2C, R3A, etc.

Prepared (Subject resp) ETHBAAT Jeno Balasko		No. 2/198 17-CRL 113 200/5 Uen		
Approved (Document resp) ETHLEL Elemer Lelik	Checked ETHGRY	Date 2015-05-15	Rev C	Reference

#### 4.27.1.2 Required TITAN Version

A TTCN-3 module can specify the minimum required version of TITAN which can be used to compile it. The format of the extension attribute is “requiresTITAN <version>”.

For example, the following snippet:

```
module X {  
    // ...  
}  
with {  
    extension "requiresTITAN R8C";  
}
```

specifies that module X has to be compiled with TITAN R8D (1.8.pl3) or later. Compiling the module with a TITAN which does not satisfy the requirement will cause a compilation error, stating that the version of the compiler is too low.

Compiling this module with TITAN R8B or below may result in a different compiler error, because the syntax of the attribute is not understood by earlier versions.

#### 4.27.1.3 Specifying the Version of a TTCN-3 Module

A module’s own version information can be specified in an extension attribute. The format of the extension attribute is

“version <version data>”

that is, the literal string “version” followed by the version information (R-state).

Example:

```
module supplier {  
    // ...  
}  
with {  
    extension "version R1A";  
}
```

The version of the module should be set to match the R-state of the product it belongs to.

For backward compatibility, the lack of version information (no extension attribute with “version” in the module’s “with” block) is equivalent to the highest possible version and satisfies any version requirement.

#### 4.27.1.4 Required Version of an Imported Module

The minimum version of an imported module can be specified with an extension attribute. The format of the extension attribute is “requires <module name> <required version>” that is, the literal string “requires” followed by the actual module name and required version.

Prepared (Subject resp) ETHBAAT Jeno Balasko		No. 2/198 17-CRL 113 200/5 Uen		
Approved (Document resp) ETHLEL Elemer Lelik	Checked ETHGRY	Date 2015-05-15	Rev C	Reference

Example:

```
module importer {  
    import from supplier all;  
}  
with {  
    extension "requires supplier R2A"  
}
```

The module name must be one that is imported into the module. Specifying a module which is not imported is flagged as an error.

In general, a module should require the full version of another module or TITAN (the R1A format). Depending on a prerelease version should be avoided whenever possible.

#### 4.27.2 Consistency Check in the Generated Code

A number of checks are performed during the build to ensure consistency of the TITAN compiler, TITAN runtime, C++ compiler used during the build. The compiler generates checking code that verifies:

- The version of the TITAN compiler matches the version of the TITAN runtime
- The platform on which the build is being performed matches the platform of the TITAN compiler
- The compiler used to build the TITAN compiler matches the compiler used to build the TITAN runtime

Some of this information (in form of C++ preprocessor macros definitions and instructions) is available to test port writers to express dependency on a particular TITAN version. When a C++ file includes a header generated by the TITAN compiler, that header includes the definitions for the TITAN runtime, including version information. These macro dependencies can be used in user-written C++ code.

- TTCN3\_VERSION is a C/C++ macro defined by the TITAN runtime headers. It contains an aggregated value of the TITAN major version, minor version and patch level. So, to express that a certain C++ file must be compiled together with TITAN R8C, the following code can be used:

```
#if TTCN3_VERSION < 10802  
#error This file requires TITAN 1.8.2  
#endif
```

- There is a preprocessor macro defined in the makefile which identifies the platform (operating system). It can be one of SOLARIS (for Solaris 6), SOLARIS8 (for Solaris 8 and above), LINUX, WIN32. Platform-dependent

Prepared (Subject resp) ETHBAAT Jeno Balasko		No. 2/198 17-CRL 113 200/5 Uen		
Approved (Document resp) ETHLEL Elemer Lelik	Checked ETHGRY	Date 2015-05-15	Rev C	Reference

code can be isolated using conditional compilation based on these macro definitions.

- If the TITAN runtime was compiled with the GNU Compiler Collection (GCC), the macro `GCC_VERSION` is defined by the TITAN runtime headers. Its value is  $10000 * (\text{GCC major version}) + 100 * (\text{GCC minor version})$ . For example, for GCC 3.4.6, `GCC_VERSION` will be defined to the value 30400; for GCC 4.1.2 it will be 40100. The value of this macro is compared during C++ compilation to the version of the compiler that was used to build TITAN itself to ensure consistency of the build. The GCC patch level is ignored for this comparison; code generated by a compiler with the same major and minor version is considered compatible. User-written code can use this value if it requires a certain version of the compiler. Alternatively, the predefined macros of the GNU compiler (`__GNUC__` and `__GNUC_MINOR__`) can be used for this purpose.
- If the TITAN runtime was built with the SunPro compiler, the compiler itself defines the `__SUNPRO_CC` macro. Please consult the compiler documentation for the possible values.

## 4.28 Negative Testing

### 4.28.1 Overview

As a TTCN-3 language extension Titan can generate invalid messages for the purpose of negative testing. The purpose is to generate wrong messages that do not conform to a given type that the SUT is expecting, and send them to the SUT and observe the SUT's reaction. In Titan only the encoding is implemented, the decoding of wrong messages is not in the scope of this feature.

In protocol testing the term of abstract syntax and transport syntax can be distinguished. In TTCN-3 abstract syntaxes are the data type definitions, while transport syntax is defined using with attributes (encode, variant) that are attached to type definitions. The negative testing feature defines modifications in the transport syntax, thus it does not affect TTCN-3 type definitions. This means that the content of the values, which shall be called **erroneous values** and **erroneous templates**, will not be modified; only their encoding will be. This encoding (transport syntax) is determined by the with attributes attached to the type definition, in case of negative testing the encoding of a value is modified by attaching special with attributes to the value which is to be encoded. TTCN-3 with attributes can be attached only to module level constants and templates; this is a limitation of the TTCN-3 standard.

Values and templates of the following structured types can be made erroneous:

- record
- set
- record of
- set of
- union

The corresponding ASN.1 types can also be used when imported from an ASN.1 module.

The following **erroneous** behaviors can be defined for the encoding of an **erroneous value** or **template**:

- omit specified fields
- change the specified field's value or both type and value
- omit all fields before or after the specified field

Prepared (Subject resp) ETHBAAT Jeno Balasko		No. 2/198 17-CRL 113 200/5 Uen		
Approved (Document resp) ETHLEL Elemer Lelik	Checked ETHGRY	Date 2015-05-15	Rev C	Reference

- insert a new field before or after the specified field

The inserted data can be either the value of a given constant or any “raw” binary data.

All encoding types (RAW, TEXT, BER, XER) supported by TITAN can be used in negative testing.

#### 4.28.2 Syntax

Erroneous attributes follow the syntax laid out in section A.1.6.6 (with statement) of the TTCN-3 standard with the following modifications:

AttribKeyword ::= EncodeKeyword | VariantKeyword | DisplayKeyword | ExtensionKeyword | OptionalKeyword | ErroneousKeyword

ErroneousKeyword ::= “erroneous”

For an erroneous attribute the syntax of the AttribSpec, a free text within double quotes, is as follows:

AttribSpecForErroneous := IndicatorKeyword [ (“ RawKeyword ”) ] “:=”  
TemplateInstance [ AllKeyword ]

IndicatorKeyword := “before” | “value” | “after”

RawKeyword := “raw”

Example (the meaning of this code will be explained in the next chapter) :

```
type record MyRec {
  integer i,
  Boolean b
}
const MyRec c_myrec := {i:=1,b:=true}
with {
  erroneous (i) "before := 123"
  erroneous (b) "value := omit"
}
```

#### 4.28.3 Semantics

The TemplateInstance is defined in the TTCN-3 standard, however the compiler will accept only constant values that have no matching symbols. The reason for using the TemplateInstance syntax is that it can contain also a type reference, allowing to define both the value and its type.

For example:

```
template MyRec t_myrec := {i:=2,b:=false}
with {
  erroneous (i) "after := MyRec.i:123"
  erroneous (i) "before := MyInteger:123"
}
```

Prepared (Subject resp) ETHBAAT Jenő Balasko		No. 2/198 17-CRL 113 200/5 Uen		
Approved (Document resp) ETHLEL Elemer Lelik	Checked ETHGRY	Date 2015-05-15	Rev C	Reference

It is important to be able to specify the type of the inserted value because the encoding attributes are attached to the type. In the example above two integer values were inserted, both integers have the same value, however one has type `MyRec.i` and the other has type `MyInteger`, this will result in different encodings of the same value if the encoding attributes for the two types are different. In TTCN-3 the encoding attributes are specified using the `with` attribute syntax, in ASN.1 BER encoding the tagging specifies the encoding attributes. If no type is given then the compiler will use the default type if it can be determined.

For example:  
erroneous (i) "value := 123"

**Important note:** the compiler will use the integer type and NOT the `MyRec.i` type.

Both references to constant values and literal values can be used:

```
const MyRec c_myrec := {i:=3,b:=true}
template MyRec t_myrec := {i:=2,b:=false}
with {
  erroneous (i) "after := c_myrec" // type determined by the definition of
  c_myrec
  erroneous (i) "before := MyRec: {i:=4,b:=true}" // type must be specified
}
```

One or more field qualifiers must be used in the `AttribQualifier` part. If more than one field is specified then the erroneous behavior will be attached to all specified fields, for example:

erroneous (i,b) "after := MyInteger:123"

In this case the value of 123 which has type `MyInteger` will be inserted both after field `i` and after field `b`.

The field qualifiers may reference any field at any depth inside a structured type that can have embedded other structured types. An example for ASN.1 types:

```
MyUnion ::= CHOICE { sof MySeqOf }
MySeqOf ::= SEQUENCE OF MySeq
MySeq ::= SEQUENCE { i INTEGER }
const MyUnion c_myunion := { ... }
with { erroneous (sof[5].i) "value := 3.14" }
This also works in case of recursive types:
type record MyRRec { MyRRec r optional }
const MyRRec c_myrrrec := { ... }
with { erroneous (r.r.r.r.r) "value := omit" }
```

If the erroneous value does not contain a field which was referred by the erroneous qualifier then the erroneous behavior specified for that field will have no effect. For example:

Prepared (Subject resp) ETHBAAT Jenő Balasko		No. 2/198 17-CRL 113 200/5 Uen		
Approved (Document resp) ETHLEL Elemer Lelik	Checked ETHGRY	Date 2015-05-15	Rev C	Reference

```
type union MyUni { integer i, boolean b }
const MyUni c_myuni := { i:=11}
with {
  erroneous (i) "value := MyUni.i:22"
  erroneous (b) "value := MyUni.b:false" // this rule has no effect
}
```

The reason for allowing the second rule is that the erroneous information can be transferred by using assignment. By assigning an erroneous constant to a local variable in a testcase or function it can be used with variables too.

For example:

```
function func() {
  var MyUni vl_myuni := c_myuni;
  vl_myuni.b := true;
  // now field b is selected in vl_myuni, therefore the erroneous rule on
  // field b will be active, the rule on field i will have no effect
}
```

The erroneous attribute data is attached to the defined constant or template and not to its fields. The fields of this erroneous constant or template do not contain any information on how they are erroneous; this information is attached to the top level. If a field is encoded on its own or is assigned to some other variable it will not contain any erroneous information.

Example:

```
module Example1
{
  type record R {
    integer i,
    R r optional
  } with { encode "TEXT" variant "BEGIN('[BEGIN]')"; variant "END('[END]')";
  variant "SEPARATOR('[*]')" }
  external function encode_R( in R pdu) return charstring with { extension
  "prototype(convert) encode(TEXT)" }
  const R r1 := { i:=1, r:={ i:=2, r:=omit } }
  with { erroneous (r.i) "value:=3" }
  control {
    log(encode_R(r1)); // output: "[BEGIN]1[*][BEGIN]3[END][END]"
    log(encode_R(r1.r)); // output: "[BEGIN]2[END]"
    // r1.r is not erroneous if used on its own!
  }
}
```

Erroneous constants can be assigned to fields of other erroneous constants and templates, however if the original field or any field embedded in that field was made erroneous then the top level erroneous data will be used and the referenced constant's erroneous data ignored. Erroneous data can be visualized as a tree that is a sub-tree of the tree of a type (in the examples the R type, which is recursive). If two erroneous sub-trees overlap then the one which was attached to the constant used as the value of that field where the overlapping happens will be ignored.

Prepared (Subject resp) ETHBAAT Jeno Balasko		No. 2/198 17-CRL 113 200/5 Uen		
Approved (Document resp) ETHLEL Elemer Lelik	Checked ETHGRY	Date 2015-05-15	Rev C	Reference

### Example:

```

module Example2
{
  type record R {
    integer i,
    R r optional
  } with { encode "TEXT" variant "BEGIN('[BEGIN]')"; variant "END('[END]')";
  variant "SEPARATOR('[*]')" }
  external function encode_R( in R pdu) return charstring with { extension
  "prototype(convert) encode(TEXT)" }
  const R r0 := { i:=0, r:=omit } with { erroneous (i) "value:=4" }
  const R r1 := { i:=1, r:=r0 } with { erroneous (r.i) "value:=3" }
  const R r2 := { i:=1, r:=r0 }
  const R r3 := { i:=1, r:=r0 } with { erroneous (r.r) "value:=R:{i:=5,r:=omit}" }
}
control {
  log(encode_R(r0)); // output: "[BEGIN]4[END]"

  log(encode_R(r1)); // output: "[BEGIN]1[*][BEGIN]3[END][END]"
  // the value of r1.r.i is determined by the erroneous attribute of r1!

  log(encode_R(r2)); // output: "[BEGIN]1[*][BEGIN]4[END][END]"
  // the value of r2.r.i is determined by the erroneous attribute of r0

  log(encode_R(r3)); // output: "[BEGIN]1[*][BEGIN]0[*][BEGIN]5[END][END][END]"
  // the value of r3.r.i is 0, the erroneous attribute on r0.i was dropped
  because
  // when r0 is used as field r3.r then this r3.r field has embedded erroneous
  data
}
}

```

### Meaning of IndicatorKeyword:

“before”: the specified value will be inserted before the specified field(s)

“value”: the specified value will be inserted instead of the value of the specified field(s)

“after”: the specified value will be inserted after the specified field(s)

In case of unions only the “value” keyword can be used.

The optional “raw” keyword that can follow the IndicatorKeyword should be used when raw binary data has to be inserted instead of a value. The specified binary data will be inserted into the encoder’s output stream at the specified position. The specified data will not be checked in any way for correctness. For convenience this binary data can be specified using TTCN-3 constants as containers. For different encoding types the different containers are as follows:

	RAW	TEXT	XER	BER	PER (encoding not yet supported)
octetstring	X	X	X	X	X

Prepared (Subject resp) ETHBAAT Jeno Balasko		No. 2/198 17-CRL 113 200/5 Uen		
Approved (Document resp) ETHLEL Elemer Lelik	Checked ETHGRY	Date 2015-05-15	Rev C	Reference

bitstring	X				X
charstring		X	X		
universal charstring			X		

Bitstrings can be used for encoding types that support the insertion of not only whole octets but also bits. For example to insert one zero bit between two fields:

```
erroneous (i) "after(raw) := '0'B"
replace a field with bits 101:
erroneous (b) "value(raw) := '101'B"
```

Charstring types can be used in case of text based encodings. For example insert some XML string between two fields:

```
erroneous (i) "after(raw) := ""<ERROR>erroneous element</ERROR>"""
```

Notice that the double quotes surrounding the charstring must be doubled because it's inside another string.

The optional "all" keyword after the TemplateInstance must be used when omitting all fields before or after a specified field, in all other cases it must not be used.

#### 4.28.4 Typical Use Cases

Types used in the examples:

```
type record MyRec {
  integer i,
  boolean b,
  charstring s length (3),
  MyRec r optional
} with { encode "RAW" variant " .... " }
type record of integer MyRecOf;
type MyRec.i MyInteger with { encode "RAW" variant " .... " }
```

Prepared (Subject resp) ETHBAAT Jenő Balasko		No. 2/198 17-CRL 113 200/5 Uen		
Approved (Document resp) ETHLEL Elemer Lelik	Checked ETHGRY	Date 2015-05-15	Rev C	Reference

#### 4.28.4.1 Discard Mandatory Fields

```
const MyRec c_myrec1 := { i:=1, b:=true, s:="str", r:=omit }
with { erroneous (i) "value := omit" }
const MyRec c_myrec2 := { i:=1, b:=true, s:="str", r:=omit }
with { erroneous (b) "after := omit all" }
const MyRecOf c_myrecof1 := { 1, 2, 3 }
with { erroneous ([1], [2]) "value := omit" }
```

#### 4.28.4.2 Insert New Fields

```
const MyRec c_myrec3 := { i:=1, b:=true, s:="str", r:=omit }
with {
  erroneous (i) "before := MyRec.i:3" // has same type as field i
  erroneous (b) "after := MyInteger:4"
}
const MyRecOf c_myrecof2 := { 1, 2, 3 }
with { erroneous ([1]) "after := MyRecOf[-]:99" }
```

#### 4.28.4.3 Ignore Subtype Restrictions

```
const MyRec c_myrec4 := { i:=1, b:=true, s:="str", r:=omit }
with { erroneous (s) "value := ""too long string"" }
```

#### 4.28.4.4 Change the Encoding of a Field

Here the TTCN-3 root type and value of field i are not changed but the encoding is changed:

```
const MyRec c_myrec5 := { i:=1, b:=true, s:="str", r:=omit }
with { erroneous (i) "value := MyInteger:1" }
```

#### 4.28.4.5 Completely Change a Field to a Different Type and Value

The second field is changed from a boolean to an integer:

```
const MyRec c_myrec6 := { i:=1, b:=true, s:="str", r:=omit }
with { erroneous (b) "value := MyInteger:1" }
```

### 4.28.5 Summary

Main features of negative testing in TITAN:

- This feature is supported only by the Function Test runtime of TITAN; when doing negative testing this feature must be turned on using the **-R** switch to switch from the default Load Test runtime to the Function Test runtime
- Performance and functionality in case of positive testing is not affected by this feature
- Existing types can be used without modifications (both TTCN-3 and ASN.1 types)
- The erroneous attribute of a value or template does not modify its content, the erroneous feature of that value or template can be seen only when encoding or logging

Prepared (Subject resp) ETHBAAT Jeno Balasko		No. 2/198 17-CRL 113 200/5 Uen		
Approved (Document resp) ETHLEL Elemer Lelik	Checked ETHGRY	Date 2015-05-15	Rev C	Reference

- ErroneousKeyword, IndicatorKeyword, RawKeyword were not introduced as new keywords in TTCN-3, thus these can be used as identifiers, the compiler is backward compatible
- The erroneousness of a value is lost when sending it between components or using it as parameter of the start() function. In TTCN-3 sending and receiving of values is done by specifying the type of data, but the erroneous information is attached to a value and not the type, thus the receiving side cannot handle erroneous information.

#### 4.28.6 Special Considerations for XML Encoding

There are a number of particularities related to negative testing of XML encoding.

\* Inserted and replaced values are encoded using the normal XML encoding functions. These values are encoded as if they were top-level types: the name of the XML element is derived from the TTCN-3 or ASN.1 type name. For built-in types (e.g. integer, boolean, universal charstring) the XML name will be according to Table 4 at the end of clause 11.25 in X.680 ([\[6\]](#)), usually the uppercased name of the type (e.g. INTEGER, BOOLEAN, UNIVERSAL\_CHARSTRING). If a particular XML name is desired, an appropriate type alias can be defined.

For example, encoding the following value:

```
type record R { integer i }  
const R c_r := { 42 } with { erroneous (i) "value := "fourty-two" " }
```

will result in the following XML:

```
<R>  
  <CHARSTRING>fourty-two</CHARSTRING>  
</R>
```

To generate an XML element with a given name, e.g. "s", the following code can be used:

```
type record R { integer i }  
type charstring s; // a type alias  
const R c_r := { 42 } with { erroneous (i) "value := s : "fourty-two" " }
```

The resulting XML will be (erroneous values highlighted in yellow):

Prepared (Subject resp) ETHBAAT Jenő Balasko		No. 2/198 17-CRL 113 200/5 Uen		
Approved (Document resp) ETHLEL Elemer Lelik	Checked ETHGRY	Date 2015-05-15	Rev C	Reference

```
<R>  
<s>fourty-two</s>  
</R>
```

A `name as "..."` TTCN-3 attribute could also be used, but that also requires a separate type.

\* By default, fields of ASN.1 SEQUENCE /TTCN-3 record are encoded as XML elements. Only those fields which have a `with { variant "attribute" }` TTCN-3 attribute applied are encoded as XML attributes. If a field having a `with { variant "attribute" }` has an erroneous value (`before/value/after`), this erroneous value will also be encoded amongst the XML attributes. However, by default the erroneous value will be encoded as an XML element; the resulting XML will not be well-formed:

```
type record R2 {  
    charstring at,  
    charstring el  
}  
with { variant (at) "attribute" }  
  
const R2 c_r2 := {  
    at := "tack", el := "le"  
} with { erroneous (at) "before := 13 " }  
results in:  
  
<R2<INTEGER>13</INTEGER> at='tack'>  
  <el>le</el>  
</R2>
```

To ensure the erroneous value is encoded as an XML attribute, a TTCN-3 type alias can be created which also has a `with { variant "attribute" }` TTCN-3 attribute. The name of the XML attribute can also be controlled either with the name of the type or a `name as "..."` TTCN-3 attribute.

```
// type record R2 as above  
type integer newatt with { variant "attribute" } // type alias for integer  
  
const R2 c_r2a := {  
    at := "tack", el := "le"  
} with { erroneous (at) "before := newatt : 13 " }  
  
<R2 newatt='13' at='tack'>  
  <el>le</el>  
</R2>
```

\* One particularity of the Titan XML encoder is that the space before the name of an XML attribute “belongs” to that attribute (it is written together with the attribute name). If the field (encoded as an XML attribute) is omitted or replaced, the space will also be removed. If a well-formed XML output is desired, the loss of the space must be compensated when using raw erroneous values (non-raw erroneous values encoded as attributes will supply the space, as can be seen in the previous example).

Prepared (Subject resp) ETHBAAT Jeno Balasko		No. 2/198 17-CRL 113 200/5 Uen		
Approved (Document resp) ETHLEL Elemer Lelik	Checked ETHGRY	Date 2015-05-15	Rev C	Reference

```
// type record R2 as above
const R2 c_r2r := {
  at := "tack", el := "le"
} with { erroneous (at) "before(raw) := "ax='xx'" " } // not compensated

<R2 ax='xx' at='tack'>
  <el>le</el>
</R2>
```

The resulting XML is not well formed.

```
// type record R2 as above
const R2 c_r2r := {
  at := "tack", el := "le"
} with { erroneous (at) "before(raw) := " ax='xx'" " }
// compensated, note space here-----^

<R2 ax='xx' at='tack'>
  <el>le</el>
</R2>
```

Now the XML is well-formed.

\* When using "before := omit all" or "after := omit all" on a member of a record which has a with { variant "useOrder" } TTCN-3 attribute, omit-before/omit-after refers to the order of the fields in the record, not the order in which they appear in the XML. In other words, useOrder has no effect on omit-before/omit-after.

```
type record UO {
  record of enumerated { id, name, price, color } order,

  integer id,
  charstring name,
  float price,
  charstring color
}
with {
  variant "element";
  variant "useOrder";
  variant "namespace as 'http://www.example.com' prefix 'exm'";
}

const UO c_uo_omit_after_price := {
  order := { id, name, color, price }, // color before price
  id := 1,
  name := "shoes",
  price := 9.99,
  color := "brown"
}
with {
  erroneous (price) "after := omit all" // after price: that's just color
}
```

This will result in

```
<exm:UO xmlns:exm='http://www.example.com'>
  <id>1</id>
  <name>shoes</name>
  <!-- color omitted here -->
  <price>9.990000</price>
```

Prepared (Subject resp) ETHBAAT Jenő Balasko		No. 2/198 17-CRL 113 200/5 Uen		
Approved (Document resp) ETHLEL Elemer Lelik	Checked ETHGRY	Date 2015-05-15	Rev C	Reference

</exm:UO>

In the XML, `color` comes before `price`. However, in record UO, `color` comes after `price`; therefore “omit all after price” does affect `color` even though `price` is the last element in the XML.

\* In a record type with { variant “useOrder” }, the first field (a record-of enumerated which controls the order of XML elements) does not appear in the generated XML. Therefore, omitting the first field has no effect.

#### 4.28.7 Special considerations for RAW encoding

There are some RAW encoding attributes (e.g. `LENGTHTO`, `POINTERTO`) that can invalidate negative testing attributes of a given constant or template. These RAW encoding attributes instruct the RAW encoder to fill some specific fields of a given constant or template being encoded during the encoding process depending on some other specific fields of a given constant or template. In this case the RAW encoding attributes and the negative testing attributes can be in conflict. If a conflict is detected by the encoder its behavior is user defined. Depending on the `errorbehavior` attribute of the given encoder function (see 4.22.4.3) the encoder can give the user an error (`errorbehavior(NEGTEST_CONFL:ERROR)`), a warning (`errorbehavior(NEGTEST_CONFL:WARNING)`) or it can ignore it as its default behavior (`errorbehavior(NEGTEST_CONFL:IGNORE)`).

The affected RAW encoding attributes and their behaviors used together with negative testing attributes are described in the following list. For detailed information about these RAW encoding attributes please check 4.23.4.

##### 1. `EXTENSION_BIT(<param>)`

It is applied even on fields added or modified by negative testing attributes.

```
type record extbitrec {
  integer f1,
  integer f2
} with { variant "EXTENSION_BIT(yes)" encode "RAW" }
const extbitrec cr := { 1, 2 } with
{ erroneous(f1) "before := 1" erroneous(f2) "value := 1" }
// The result will be '010181'O.
```

##### 2. `EXTENSION_BIT_GROUP(<param1, param2, param3>)`

Prepared (Subject resp) ETHBAAT Jenő Balasko		No. 2/198 17-CRL 113 200/5 Uen		
Approved (Document resp) ETHLEL Elemer Lelik	Checked ETHGRY	Date 2015-05-15	Rev C	Reference

If a specific extension bit group is somehow affected by negative testing attributes (e.g. some of the elements of a given extension bit group were modified, new fields were added into it) a warning<sup>16</sup> will be given and the extension bit group will be ignored.

```
type record extbitgrouprec {
  integer f1,
  integer f2,
  integer f3,
  integer f4,
  integer f5,
  integer f6
} with {
  variant "EXTENSION_BIT_GROUP(yes, f1, f3)"
  variant "EXTENSION_BIT_GROUP(yes, f5, f6)"
  encode "RAW"
}
const extbitgrouprec cr := { 1, 2, 3, 4, 5, 6 } with {
  erroneous(f1) "before := 1"
  erroneous(f4) "value := 1"
  erroneous(f6) "after := 1" }
// None of the extension bit groups are affected.
// The result will be '0101028301058601'0.
```

### 3. LENGTHTO(<param>) and LENGTHINDEX(<param>)

If any of the fields the length is calculated from or the field the result is stored into are affected by negative testing attributes a warning will be given and the length calculation will be ignored. In this case the value of the field the result is stored into is undefined, but it's possible to set its value using negative testing attributes.

```
type record lengthtorec1 {
  integer f1
  with { variant "" encode "RAW" }
}
type record lengthtorec2 {
  integer f1 optional,
  lengthtorec1 f2 optional,
  charstring f3 optional,
  charstring f4 optional
} with {
  variant (f2) "LENGTHTO(f3, f4)"
  variant (f2) "LENGTHINDEX(f1)"
  encode "RAW"
}
const lengthtorec2 cr := { 1, { 2 }, "", "one" } with {
  erroneous(f1) "before := 1" erroneous(f2) "after := 1" }
// No conflict, LENGTHTO is calculated normally.
// The result will be '010103016F6E65'0.
```

### 4. POINTERTO(<param>)

---

<sup>16</sup> Depending on the `errorbehavior` attribute of the given encoder. (For simplicity, warning will be used throughout the text.)

Prepared (Subject resp) ETHBAAT Jenő Balasko		No. 2/198 17-CRL 113 200/5 Uen		
Approved (Document resp) ETHLEL Elemer Lelik	Checked ETHGRY	Date 2015-05-15	Rev C	Reference

If any of the fields between (and including) the pointer and the pointed fields are affected by negative testing attributes (e.g. new fields were added in-between) a warning will be given and the pointer calculation will be ignored. In this case the value of the pointer field will be undefined, but it's possible to set its value using negative testing attributes.

```
type record pointertorec {
  integer f1,
  charstring f2,
  charstring f3
} with { variant (f1) "POINTERTO(f3)" encode "RAW" }
const pointertorec cr := { 1, "dinner", "bell" } with {
  erroneous(f1) "before := 1" erroneous(f3) "after := 1" }
// No conflict, POINTERTO is calculated normally.
// The result will be '010264696E6E657262656C6C01'O.
```

#### 5. PRESENCE(<param>)

Even if the optional field or any of the fields referenced in the presence indicator list are affected by negative testing attributes a warning will be given and the fields will not be modified according to the PRESENCE RAW encoding attribute, it will be completely ignored.

```
type record presencerec1 {
  integer f1
} with { variant "" encode "RAW" }
type record presencerec2 {
  integer f1,
  presencerec1 f2,
  integer f3,
  integer f4 optional
} with { variant (f4) "PRESENCE(f1 = 9, f2.f1 = 99, f3 = 1)"
  encode "RAW" }
const presencerec2 cr := { 1, { 2 }, 3, 4 } with {
  erroneous(f1) "after := 1" erroneous(f4) "after := 1" }
// No conflict.
// The result will be '090102030401'O.
```

#### 6. TAG(<param>) and CROSSTAG(<param>)

If the field the attribute belongs to or any of the fields referenced in the presence indicator list are affected by negative testing attributes a warning will be given and the fields will not be modified according to the TAG and CROSSTAG RAW encoding attributes, it will be completely ignored.

```
type record tagrec1 {
  integer f1
} with { variant "" encode "RAW" }
type record tagrec2 {
  tagrec1 f1,
  tagrec1 f2,
  tagrec1 f3
} with { variant "TAG(f1, f1 = 1; f2, f1 = 2)" encode "RAW" }
const myrec17 cmr26 := { { 1 }, { 2 }, { 3 } } with {
  erroneous(f1) "after := 1" erroneous(f2) "after := 1"
  erroneous(f3) "value := 33" }
// No conflict.
// The result will be '0101020121'O.
type record crosstagrec1 {
```

Prepared (Subject resp) ETHBAAT Jenő Balasko		No. 2/198 17-CRL 113 200/5 Uen		
Approved (Document resp) ETHLEL Elemer Lelik	Checked ETHGRY	Date 2015-05-15	Rev C	Reference

```
integer f1,
integer f2
} with { variant "" encode "RAW" }
type union crosstaguni {
  crosstagrec1 f1,
  crosstagrec1 f2
} with { variant "" encode "RAW" }
type record crosstagrec2 {
  integer f1,
  integer f2,
  crosstaguni f3
} with {
  variant (f3) "CROSSTAG(f1, { f1 = 1, f1 = 11, f2 = 6 };
  f2, f1 = 3)" encode "RAW" }
const crosstagrec2 cr := { 1, 2, { f1 := { 3, 4 } } } with {
  erroneous(f1) "before := 1" erroneous(f2) "after := 1"
  erroneous(f3) "after := 9" }
// No conflict.
// The result will be '01010201030409'O.
```

## 4.29 Testcase Stop Operation

The testcase stop operation defines a user defined immediate termination of a test case with the test verdict **error** and an optional associated reason for the termination. Such an immediate stop of a test case is required for cases where a user defined behavior that does not contribute to the test outcome behaves in an unexpected manner which leads to a situation where the continuation of the test case makes no more sense.

Syntax: testcase “.” stop [ “(“ { ( FreeText | TemplateInstance ) [ “,” ] “)” ]

Example:

```
testcase.stop("Unexpected Termination");
// The testcase stops with a Dynamic Testcase Error and
the parameter string is
// written to the log.
```

## 4.30 Catching Dynamic Test Case Errors

In load testing applications premature termination of test cases due to unforeseen errors is a serious issue because when a dynamic test case error (DTE) occurs there was no way to handle it on TTCN-3 level, thus the test case is stopped with an error verdict. The mechanism of catching DTEs is very similar to exception handling used in other languages: there is a try statement block which contains the guarded code and immediately after it there is a catch statement block which contains the code that is executed if a DTE occurred in the guarded statement block. When a DTE occurs in a statement the rest of the statements in that block are skipped and control is transferred to the 1<sup>st</sup> statement of the catch block. Two TITAN specific keywords were introduced for this purpose: *@try* and *@catch*, these start with a “@” to avoid backward compatibility issues (new keywords clashing with identifiers used in existing code) and to differentiate them from standard TTCN-3 keywords.

Prepared (Subject resp) ETHBAAT Jenő Balasko		No. 2/198 17-CRL 113 200/5 Uen		
Approved (Document resp) ETHLEL Elemer Lelik	Checked ETHGRY	Date 2015-05-15	Rev C	Reference

### Syntax:

```
function MyFunc() {  
    @try { // this is the guarded block, all DTEs are caught here  
        <statements>  
    }  
    @catch(dte_str) { // dte_str will contain the error message of the DTE  
        <statements>  
    }  
}
```

The identifier `dte_str` becomes an invisible variable definition in the `@catch` block, the code is semantically equivalent to:

```
@catch {  
    var charstring dte_str := <DTE error message>;  
    <statements>  
}
```

This can be used as a normal `charstring` type variable whose scope is the `@catch` statement block.

### Example:

```
// The predefined str2int() function causes a DTE if the input is invalid,  
// this wrapper function makes it safe to use it on possibly invalid input  
strings  
function safe_str2int(in charstring int_str, in integer defval) return integer  
{  
    @try {  
        return str2int(int_str);  
    }  
    @catch(err) {  
        return defval;  
    }  
}  
  
// Here we check if the DTE was because of a division by zero, if not then  
// the DTE with the same message is created again, so that any other DTE will  
// stop the execution of the test case with the original error message.  
// If it was a division by zero then the verdict is set to fail.  
external function throw(in charstring msg);  
testcase TC(in integer i) runs on MyComp {  
    @try {  
        i := 10 / i;  
        somefunction(); // this function might cause other DTEs  
        setverdict(pass); // this line is reached only if there was no DTE  
    }  
    @catch(err) {  
        if (match(err, pattern "*division by zero*")) {  
            log("division by zero detected");  
            setverdict(fail); // the verdict is fail instead of error  
        } else {  
            throw(err); // external function used to re-throw the DTE  
        }  
    }  
}  
  
// external function can be used to re-throw the error in the catch block with  
// a  
// modified or original (as in the example above) error message, the C++  
// implementation:  
void throw_(const CHARSTRING& msg) {  
    TTCN_error("%s", (const char*)msg);  
}
```

`@try-@catch` blocks can be nested. In this example minor DTEs are ignored and the `// for` loop continues but in case of a major error the DTE is re-thrown an

Approved (Document resp) ETHLEL Elemer Lelik	Checked ETHGRY	Date 2015-05-15	Rev C	Reference

```
caught by // the outer catch which also terminates the test case with a fail
verdict:
testcase TC() runs on MyComp {
    @try {
        for (var integer i:=0; i<100; i:=i+1) {
            @try {
                <statements that can cause DTEs>
            }
            @catch(dte_str) {
                if (match(err, <some pattern for minor errors>) {
                    log("minor error ", dte_str, " ignored, continuing load test...");
                } else {
                    throw(dte_str);
                }
            }
        }
    }
    setverdict(pass);
}
@catch(dte_msg) {
    log("Something went very wrong: ", dte_msg);
    setverdict(fail);
}
}
```

## 4.31 Lazy Parameter Evaluation

This feature was developed for load testing, to speed up function execution by not evaluating the actual parameter of the function when its value is not used inside the function. It speeds up execution when relatively large expressions are used as “in” actual parameters. In the normal case the parameter is always evaluated before the execution of the function starts, even if the parameter is never used. In case of lazy parametrization the parameter is not evaluated if it’s never used and it is evaluated exactly once when it is used. It is important to note that the values referenced by the expression may change before the evaluation actually happens. This feature can be used only in case of “in” parameters, in case of “inout” and “out” parameters expressions cannot be used and thus it would be useless. The new titan specific keyword `@lazy` was introduced, this must be placed right before the type in the formal parameter. This can be used for both values and templates of all types.

An example logging function that does not evaluate its message parameter if not used:

```
function MyLog(in @lazy charstring message) runs on MyComp {
    if (logEnabled) {
        log(message);
    }
}
```

calling the function with an expression:

```
MyLog( "MyLog: " & log2str(some_large_data_structure) );
```

Prepared (Subject resp) ETHBAAT Jeno Balasko		No. 2/198 17-CRL 113 200/5 Uen		
Approved (Document resp) ETHLEL Elemer Lelik	Checked ETHGRY	Date 2015-05-15	Rev C	Reference

If `logEnabled` is false the above actual parameter will not be evaluated.

Example for evaluation:

```
type component MyComp { var integer ci := 0; }
function MyFuncDieIfZero() runs on MyComp return integer {
  if (ci==0) { testcase.stop; } // die if the component variable is zero
  return ci;
}
function MyLazyFunc(in @lazy integer pi) runs on MyComp {
  ci := 1;
  log(pi); // first use of pi -> it is evaluated, ci==1, 3*1=3 is logged
  ci := 2;
  log(pi); // second use of pi -> not evaluated, the value 3 is used again
}
```

Calling the function:

```
MyLazyFunc(3*MyFuncDieIfZero()); // the MyFuncDieIfZero() function is not
// evaluated here,
ci==0 here, it would die
```

In the above example we see that `MyFuncDieIfZero()` can also have a side effect if `ci==0`. If the actual parameter expression has a side effect it must be used carefully in case of lazy formal parameter, because it is either executed at a later time or never executed at all.

Currently the only limitation is that function reference types cannot have lazy formal parameters, thus functions with lazy parameters cannot be invoked.

## 4.32 Differences between the Load Test Runtime and the Function Test Runtime

The Function Test runtime sometimes provides extra features that the default Load Test runtime doesn't (due to it being optimized for performance). One of these features, negative testing for encoders, was already discussed in section 4.28.

### 4.32.1 Referencing `record` of elements through function parameters

Passing a `record` of and one (or more) of its elements as `out` and/or `inout` parameters of the same function means that changes made inside the function to either of these parameters can cause changes in the others. Lowering the size of the `record` of (inside the function) can cause some of the other parameters to become `unbound` (this functionality only works in the Function Test runtime).

Example:

```
type record of integer RoI;
```

Prepared (Subject resp) ETHBAAT Jeno Balasko		No. 2/198 17-CRL 113 200/5 Uen		
Approved (Document resp) ETHLEL Elemer Lelik	Checked ETHGRY	Date 2015-05-15	Rev C	Reference

```
function f_param_ref(inout RoI p_roi, inout integer p_ref)
{
    p_roi := { 10 };
    log(p_ref);      // <unbound>
    p_ref := 20;
    log(p_roi);      // { 10, <unbound>, <unbound>, 20 }
}

...

// function call:
var RoI v_roi := { 1, 2, 3, 4, 5 };
f_param_ref(v_roi, v_roi[3]);
```

This also works if the `record of` or its element(s) are embedded into other structures, and these structures are passed as the function's parameters. It also works if the `record of` is an optional field of a `record` or `set`, and the field is set to `omit` inside the function.

This functionality does not work for templates.

**Warning:** a side effect of this feature is that, in the Function Test runtime, passing an element outside of the `record of`'s bounds as an `out` or `inout` parameter does not extend the `record of` if the function doesn't change the parameter, instead the size of the `record of` will remain unchanged. In the Load Test runtime this would change the size of the `record of` to the value of the index, and the `record of` would contain unbound elements at its end.

Example (filling an array up by passing the element after the last as a function parameter):

```
type record of integer RoI;

function f_fill_array(out integer p_elem, in integer p_val) return boolean
{
    if (p_val < 3) {
        p_elem := p_val;
        return true;
    }
    return false;
}

...

// the function call:
var integer v_val := 0;
var RoI v_roi := { };
while (f_fill_array(v_roi[sizeof(v_roi)], v_val)) {
    v_val := v_val + 1;
}

// Results:
// In the Function Test runtime the array would contain { 0, 1, 2 } and its
// sizeof would return 3
// In the Load Test runtime the array would contain { 0, 1, 2, <unbound> }
// and its sizeof would return 4
```

Prepared (Subject resp) ETHBAAT Jeno Balasko		No. 2/198 17-CRL 113 200/5 Uen		
Approved (Document resp) ETHLEL Elemer Lelik	Checked ETHGRY	Date 2015-05-15	Rev C	Reference

#### 4.32.2 Compatibility of record of types

In the Function Test runtime `record of` and `set of` types of the same element type are compatible with each other. In the Load Test runtime this is only true for the following (TTCN-3) element types:

- `boolean`
- `integer`
- `float`
- `bitstring`
- `hexstring`
- `octetstring`
- `charstring`
- `universal charstring`

The `record ofs` / `set ofs` are also compatible for the ASN.1 equivalents of the previously listed element types:

- `BOOLEAN`
- `INTEGER`
- `REAL`
- `BIT STRING`
- `OCTET STRING`
- `NumericString`
- `PrintableString`
- `IA5String`
- `VisibleString`
- `Unrestricted Character String`
- `UTCTime`
- `GeneralizedTime`
- `UTF8String*`
- `TeletexString*`
- `VideotexString*`
- `GraphicString*`
- `GeneralString*`
- `UniversalString*`
- `BMPString*`
- `ObjectDescriptor*`

There is one exception to this rule: records/sets of universal charstring (or any of its ASN.1 equivalents, marked with \*) are not compatible with other records/sets of universal charstrings in the Load Test runtime, if they or their element type have the XER coding instruction `'anyElement'`.

Example:

```
type record of integer RoI1;  
type record of integer RoI2;
```

```
type record Date {  
    integer month,  
    integer day,  
    integer year  
}
```

Prepared (Subject resp) ETHBAAT Jenő Balasko		No. 2/198 17-CRL 113 200/5 Uen		
Approved (Document resp) ETHLEL Elemer Lelik	Checked ETHGRY	Date 2015-05-15	Rev C	Reference

```
type record of Date Dates1;
type record of Date Dates2;

...

var RoI1 roi1 := { 1, 2, 3 };
var RoI2 roi2 := roi1; // works in both runtimes

var Dates1 dates1 := { { 3, 30, 2015 }, { 3, 31, 2015 } };
var Dates2 dates2 := dates1; // works in the Function Test runtime, displays
                             // a compilation error in the Load Test runtime
```

### 4.33 Profiling and code coverage

The TTCN-3 Profiler measures the execution time of TTCN-3 code lines and functions, and determines the number of times code lines and functions were executed (including tracking lines/functions that were never executed).

The profiler stores the data it has collected in a database file in JSON format.

When a TTCN-3 project (with profiling enabled) finishes execution, a statistics file is generated, containing the information gathered by the profiler in various representations.

#### 4.33.1 Activating the TTCN-3 Profiler

The profiler can be activated in the desired TTCN-3 modules with the compiler option `-z`, followed by a text file containing the list of TTCN-3 file names to be profiled separated by new line characters (this list can also contain `ttcnpp` files).

The compiler generates extra code for profiling and code coverage in the code generated for these modules.

The compiler option `-L` must also be specified.

Usage example (activating the profiler in all modules in the current folder):

```
ls -l *.ttcn > prof_files.txt
ttn3_compiler -L -z prof_files.txt *.ttcn
```

Once activated the profiler's behavior can be customized through the `[PROFILER]` section in the configuration file (for more details see section 7.12).

#### 4.33.2 Gathered information

The profiler measures two things: the total execution time of a code line or function (the amount of time the TTCN-3 Executor spent running this code line/function) and the total execution count of a code line or function (the number of times a code line/function was executed).

The profiler measures all times with microsecond precision.

Prepared (Subject resp) ETHBAAT Jenö Balasko		No. 2/198 17-CRL 113 200/5 Uen		
Approved (Document resp) ETHLEL Elemer Lelik	Checked ETHGRY	Date 2015-05-15	Rev C	Reference

The profiler classifies the following TTCN-3 elements as ‘functions’: functions, testcases, altsteps, parameterized templates and the control part (in this case the function’s name is `control`). External functions are not considered ‘functions’ by the profiler, they are treated as regular TTCN-3 commands.

The ‘code lines’ contain any line with at least one TTCN-3 command. The first line of a function is always a code line (even if it doesn’t contain any commands), and measures the time between the beginning of the function’s execution and the beginning of the execution of the first line in the function. The time between the end of the last line’s execution and the end of the function’s execution is not measured separately, it is simply added to the last line’s total time.

In the following example there are 10 code lines and 3 functions:

```
module prof1 {  
  
  type component C {}  
  
  const integer c1 := 7;    // line 5  
  
  function f1(inout integer x) runs on C    // line 7, function 'f1'  
  {  
    x := x + c1;    // line 9  
  }  
  
  testcase tc1() runs on C    // line 12, function 'tc1'  
  {  
    var integer x := 6;    // line 14  
    f1(x);    // line 15  
    log(x);    // line 16  
    x := x + 1;    // line 17  
  }  
  
  control {    // line 20, function 'prof1'  
    execute(tc1());    // line 21  
  }  
  
}
```

#### 4.33.2.1 Gross and net times

The line times measured by the profiler are gross times, meaning they also contain the execution times of all function calls in that line, not just the execution of the line itself. A setting in the configuration file can change the profiler to measure net line times instead, in which case the execution times of function calls will not be added to lines’ total execution times.

The same is true for functions: by default the execution times of function calls inside the function are included in the function’s total time. A configuration file setting can change the profiler to measure net function times, in which case the function’s total time will not contain the times of embedded function calls.

Prepared (Subject resp) ETHBAAT Jenő Balasko		No. 2/198 17-CRL 113 200/5 Uen		
Approved (Document resp) ETHLEL Elemer Lelik	Checked ETHGRY	Date 2015-05-15	Rev C	Reference

If a function is defined in a module where profiling is not activated (does not appear in the compiler option's file list), and is called from a module where profiling is activated, then that function call acts as if it were a regular code line (its execution time will be added the caller line's and function's total time in both cases).

#### 4.33.3 Contents of the statistics file

The statistics file contains lists of either code lines or functions with the data gathered for each line or function.

The lists start with a title specifying what data the list contains. The titles are preceded and followed by a line made of dashes (-).

Each element in a list starts with the gathered data (either the total execution time, the execution count, or both) or the average time it took for the code line or function to execute (followed by the gathered data this was calculated from in brackets: total time / execution count). The second part of a list element specifies the code line or function the data belongs to in the following format:

<TTCN-3 file name>:<line number> [<function name>]

The function name is only displayed for functions and for code lines that mark the beginning of a function. The line number for functions is the line the function starts in.

The lists either contain raw data or sorted data. Raw data is sorted ascendingly by line number and is always grouped by module (the modules are separated by lines made of dashes). Sorted data is sorted descendingly by either total time, execution count or average time, and can be global or grouped by module.

Here is an example of the sorted average times in the previously mentioned module `prof1` (where `tc1` is called directly from the configuration file and `f1` is called 2 more times from other modules):

```
-----  
- Average time / execution of code lines, sorted, per module -  
-----  
0.000362s      (0.000362s / 1)          prof1.ttcn:17  
0.000222s      (0.000222s / 1)          prof1.ttcn:12 [tc1]  
0.000050s      (0.000050s / 1)          prof1.ttcn:16  
0.000007s      (0.000021s / 3)          prof1.ttcn:5  
0.000004s      (0.000012s / 3)          prof1.ttcn:9  
0.000001s      (0.000003s / 3)          prof1.ttcn:7 [f1]  
0.000001s      (0.000001s / 1)          prof1.ttcn:14  
0.000001s      (0.000001s / 1)          prof1.ttcn:15  
-----  
...
```

The statistics file contains the following lists:

Prepared (Subject resp) ETHBAAT Jenő Balasko		No. 2/198 17-CRL 113 200/5 Uen		
Approved (Document resp) ETHLEL Elemer Lelik	Checked ETHGRY	Date 2015-05-15	Rev C	Reference

- Number of code lines and functions – this list is an exception from the previously mentioned rules; this list contains one element per module and specifies the number of code lines and function in that module, ending with a line made of dashes and the total number of code lines and functions

Example:

```
-----  
- Number of code lines and functions -  
-----  
prof1.ttcn:      10 lines,      3 functions  
prof2.ttcn:      13 lines,      4 functions  
prof3.ttcn:      13 lines,      3 functions  
-----  
Total:           36 lines,     10 functions
```

- Raw data (4 lists) – one list containing both the total time and execution count for each code line and one list containing their average times, followed by one list with the total times and execution counts of functions and one list with their average times
- Sorted total times (4 lists) – one list for code lines grouped by module and one (global) for the code lines in all modules, followed by the same for functions (these lists only contain the total execution time of each code line and function)
- Sorted execution counts (4 lists) – same as the lists of total times
- Sorted average times (4 lists) – same as the previous two
- Top 10 total times, execution counts and average times (6 lists) – these contain the first 10 entries from every sorted global list (in the order mentioned in the previous three)
- Unused code lines and functions (2 lists) – these don't contain any data, only the code line / function specification, they are grouped by module, first the unused lines, then the functions

Any of these lists can be disabled in the configuration file (either one by one or grouped).

#### 4.33.4 Starting and stopping the profiler

The profiler can be stopped using the `@profiler.stop` command. When stopped the profiler does not measure new data. This command has no effect if the profiler is already stopped.

A stopped profiler can be restarted with the `@profiler.start` command. Similarly, this has no effect if the profiler is already running.

Prepared (Subject resp) ETHBAAT Jenö Balasko		No. 2/198 17-CRL 113 200/5 Uen		
Approved (Document resp) ETHLEL Elemer Lelik	Checked ETHGRY	Date 2015-05-15	Rev C	Reference

The execution count of a function is measured at the start of the function, thus if the profiler is stopped when the function is called, its call will not be measured, even if the profiler is restarted during the function's execution.

Starting and stopping the profiler only affects profiling and code coverage in the current component.

The boolean value `@profiler.running` stores the state of the profiler in the current component (`true` if it's running or `false` if it's stopped).

By default the profiler is automatically started for each component when the program starts, this can be changed in the configuration file.

Usage example (a function that's always profiled and returns the profiler to its original state):

```
function fl(inout integer x) runs on C
{
    var boolean stop_prof := not @profiler.running;
    @profiler.start;
    x := x + 1;
    if (stop_prof) {
        @profiler.stop;
    }
}
```

## 5 Supported ASN.1 Constructs and Limitations

All kind of comments defined in X.680 clause 11.6 can be used ([\[6\]](#)).

All tagging environment is supported: `IMPLICIT`, `EXPLICIT` and also `AUTOMATIC`.

The type constraints are ignored. The BER (de)coding is not influenced by the constraints, except for the table constraints. For details, see section [6.4](#).

[Table 10](#) (page [186](#)) summarizes how the different ASN.1 types are supported.

There is a special type: `ANY`. It has the same interface as the `OCTET STRING`, but during the decoding, it accepts any valid encoded message, and its value will be the complete TLV. This type is very useful if the protocol carries an encoded message.

Value sets are not supported as they are closely related to type constraints. Value set assignments in modules are parsed, but silently ignored. However, value set fields of information object classes (both fixed and variable type ones) cannot even be parsed, syntax errors are reported when processing such fields. As a consequence of this the information objects governed by such classes cannot be parsed either.

Variable type value fields of information object classes are not supported. Processing of the class definition results in syntax error.

Prepared (Subject resp) ETHBAAT Jeno Balasko		No. 2/198 17-CRL 113 200/5 Uen		
Approved (Document resp) ETHLEL Elemer Lelik	Checked ETHGRY	Date 2015-05-15	Rev C	Reference

A missing `IMPORTS` keyword implies an implicit import of all symbols from all modules according to the ASN.1 recommendation X.680 [4]. However, the missing `IMPORTS` keyword is interpreted by TITAN as an empty `IMPORTS;` keyword, thus, no symbols at all will be imported from any of the modules.

Table 10 Supported ASN.1 types

## 6 Compiling TTCN-3 and ASN.1 Modules

You can translate your TTCN-3 and ASN.1 modules to C++ source code using the program compiler.

### 6.1 Command Line Syntax

This section describes the options allowed in the command line of the compiler and the Makefile generator.

#### 6.1.1 Compiler

The program compiler resides in the directory `$TTCN3_DIR/bin`.

The command line syntax of the compiler is the following:

```
compiler [ -abCdEfGijlLnPqrRstUwxXyY ] [ -K file ] [ -z file ] [ -N old|new ]  
[ -o dir ] [ -V n ] [ -P toplevel pdu ] [ -Qn ] [ -U none|type ] ...  
[ -T ] module.ttcn [ -A ] module.asn ... [ - module.ttcn module.asn ... ]
```

or

```
compiler -v
```

or

```
compiler --ttcn2json [ -jf ] ... [ -T ] module.ttcn [ -A ] module.asn ...  
[ - schema.json ]
```

The compiler takes the name of files containing TTCN-3 and ASN.1 modules as arguments. The usual and recommended suffix is `.ttcn` for TTCN-3 and `.asn` for ASN.1 source files, but it is not stringent<sup>17</sup>. For TTCN-3 and ASN.1 modules, the names of the output files are the same as the name of the modules, except for the suffixes which are `.hh` and `.cc`.

Please note that in the ASN.1 module names hyphens are replaced by underscore character.

**WARNING!** If you have a modular test suite, you have to translate all modules of the test suite in one step, i.e. you have to specify all TTCN-3 and ASN.1 files in the argument list.

The switches denoted by square brackets are optional. More than one option may be merged for abbreviation. For example, `-r -u` has exactly the same meaning as `-ru`.

The following command line options are available (listed in alphabetical order):

---

<sup>17</sup> Other tool vendors may use `.mp`, `.3mp` or `.asn1` suffixes as well.

Prepared (Subject resp) ETHBAAT Jeno Balasko		No. 2/198 17-CRL 113 200/5 Uen		
Approved (Document resp) ETHLEL Elemer Lelik	Checked ETHGRY	Date 2015-05-15	Rev C	Reference

-a

Enables the generation of Basic XML encoder/decoder functions for ASN.1 types. By default, these encoder/decoder functions are omitted because Basic XER has limited practical use.

-A file

Forces the interpretation of file as an ASN.1 module.

-b

Disables the generation of BER encoder/decoder routines for all ASN.1 types.

-c

This switch is designed to help identifying compilation failures caused by mismatched versions of TTCN-3 and/or ASN.1 modules. If the compilation fails, the compiler will display the module checksums (and module version information, if available) computed during compilation.

-d

This switch changes the way fields of ASN.1 SEQUENCE /SET types with DEFAULT values are handled. Without -d, the runtime handles the encoding and decoding of default values in a way that is consistent with DER and CER. With -d in effect, the ETS is responsible for the handling of fields with default values. This makes it possible to send encodings which are valid BER but not valid DER/CER and to verify that the SUT has performed the encoding correctly (note that without -d, the cases marked \* and \*\* below cannot be distinguished in TTCN code).

Sending	Without -d	With -d
Explicit value	Send value	Send value
Default value	Do not send (omit)	Send default value
omit	N/A	Do not send (omit)

Receiving	Without -d	With -d
Receive explicit value	TTCN sees value	TTCN sees value
Receive default value	TTCN sees default value*	TTCN sees default value
Omitted	TTCN sees default value**	TTCN sees 'omit'

For more details, see [14]

Warning! Existing tests may behave differently when compiled with -d. Every behavior without -d can be duplicated when compiled with -d.

-f

Forces the compiler to overwrite (update) the output files even if they exist or the contents of them will be identical. Without this flag the output C++ header and source files will be overwritten only if their contents change compared to the previous version.

Prepared (Subject resp) ETHBAAT Jeno Balasko		No. 2/198 17-CRL 113 200/5 Uen		
Approved (Document resp) ETHLEL Elemer Lelik	Checked ETHGRY	Date 2015-05-15	Rev C	Reference

-g

The compiler error/warning messages will contain the starting line number, and the starting column number if available. This option provides compatibility with the GNU compiler and many tools which are able to interpret its output (including Eclipse).

If both -g and -i are specified, -g takes precedence.

-i

The compiler error/warning messages will contain only the line numbers, the column numbers will remain hidden. This option provides backward compatibility with the error message format of earlier versions.

-j

Disables the generation of JSON encoder/decoder routines for all TTCN-3 types.

-K file

Enable code coverage for TTCN-3 modules listed in `file`. `file` is an ASCII text file which contains one file name per line. The set of files in `file` needs to be a subset of the TTCN-3 modules listed on the command line.

-l

Instructs the compiler to generate source file and line information (that is, `#line` directives) into the output code so that the error messages of the C++ compiler refer back to the lines of the original TTCN-3 input module. This makes finding the reason of C++ error messages easier. This option has effect only in the equivalent C++ code of TTCN-3 functions, test cases and control parts and this feature is not provided in other TTCN-3 definitions such as `types`, `constants` or `templates`. WARNING! This is an experimental feature and the C++ compiler may report misleading error messages that refer to totally wrong (e.g. non-existent) TTCN-3 line numbers. In these cases please turn off this flag, repeat the compilation and analyze the generated code manually. Without this flag, the compiler also inserts the source code information for the better understanding of C++ error messages, but only as C++ comments. This option has no impact on the run-time performance of the generated code. The compiler performs full semantic analysis on its entire input; it normally does not generate erroneous C++ code. So this option became obsolete and will be removed in future versions.

-L

Instructs the compiler to add source file and line number information into the generated code to be included in the log during execution. This option is only a prerequisite for logging the source code information. The run-time configuration file parameters `OptionsSourceInfoFormat` and `LogEntityName` in section [LOGGING] have also to be set appropriately (see section [7.2](#)).

This feature can be useful for finding the cause of dynamic test case errors in fresh TTCN-3 code. Using this option enlarges the size of the generated

Prepared (Subject resp) ETHBAAT Jenő Balasko		No. 2/198 17-CRL 113 200/5 Uen		
Approved (Document resp) ETHLEL Elemer Lelik	Checked ETHGRY	Date 2015-05-15	Rev C	Reference

code a bit and reduces execution speed slightly; therefore it is not recommended when the TTCN-3 test suite is used for load generation.

`-o dir`

The output files (including Test Port skeletons) will be placed into the directory specified by `dir`. Otherwise, the current working directory is the default.

`-p`

Instructs the compiler only to parse the given TTCN-3 and ASN.1 modules. This will detect only the syntax errors in them because semantic checks are not performed. The presence of all imported modules is not necessary, thus, it is allowed (and recommended) to parse the modules one-by-one. All options that influence the code generation are silently ignored when used together with `-p`.

Note: This option includes complete syntax checks for TTCN-3 modules, but in ASN.1 there are some special constructs (e.g. the user-defined syntaxes) that cannot be parsed without semantic analysis. So there is no guarantee that an ASN.1 module is free of syntax errors if it was analyzed with compiler using the `-p` flag.

`-P top_level_pdu ...`

Defines a top-level pdu that must have the format  
`module-name.identifier`.

If this switch is used, then only the defined top-level PDU(s) and the referenced assignments are checked and included in code generation, the other ASN.1 assignments are skipped. You can define not only types but any kind of ASN.1 assignments.

`-q`

Quiet mode. Equivalent to the flag `-v 0`.

`-Q n`

Quit after `n` errors (`n` must be a positive integer). The compiler will abort after encountering the specified number of errors. Note that the errors count is cumulative across all modules. Using this option may cause some modules not to be analyzed at all (if previous modules “used up” all the allowed errors).

`-r`

Disables the generation of RAW encoder/decoder routines for all TTCN-3 types.

`-R`

Instructs the compiler to generate code for use with the function test runtime. The size of the generated code is significantly reduced, much of the functionality was migrated to the runtime. The generated C++ code has to be compiled using the `TITAN_RUNTIME_2` symbol and has to be linked with the function test version of the runtime library. For example instead of the library file `libttn3.a` the alternative `libttn3-rt2.a` file must be used. The included c++ header files are the same.

Prepared (Subject resp) ETHBAAT Jenő Balasko		No. 2/198 17-CRL 113 200/5 Uen		
Approved (Document resp) ETHLEL Elemer Lelik	Checked ETHGRY	Date 2015-05-15	Rev C	Reference

-s

Instructs the compiler to parse the given TTCN-3 and ASN.1 modules and perform semantic analysis on them, but not to generate C++ output. The list of given modules shall be complete so it is not allowed to import from a module that is not in the list.

All options that influence the code generation are silently ignored when used together with -s.

Note: The TTCN-3 semantic analyser of the compiler is still under development, thus, it is not capable of detecting every kind of semantic error.

-S

Suppress context information. When the compiler reports an error or warning, it also reports context information (italic in the example below):

```
quitter3.ttcn: In TTCN-3 module `quitter3':
quitter3.ttcn:11.3-23.3: In control part:
quitter3.ttcn:12.11-30: In variable definition `v_r':
quitter3.ttcn:12.20-28: error: Reference to non-existent field `z' in record
value for type `@quitter3.R'
```

The -S option causes the compiler to output only the error (last line), without the preceding lines of context.

-t

Generates Test Port skeleton header and source files for all port types in the input TTCN-3 modules. Existing Test Port files will not be overwritten unless the -f option is used.

Note: In versions 1.1 and earlier this was the default behavior of the compiler, but if the existing Test Port source files were stored in a different directory, the generated new skeletons could be confusing.

-T file

Forces the interpretation of file as a TTCN-3 module.

-u

Forces the compiler to insert duplicated underscore characters in all output file names. This option turns on the compatibility mode with versions 1.1 or earlier.

-U none|type

Selects the code splitting mode for the generated code. The option “none” means that the old code generation method will be used. When using the option “type”, TITAN will create separate source files for the implementation code of the following types (for each module): sequence, sequence of, set, set of, union. In this case a common header file and a source file holding everything else will also be created.

-v

Prints version and license key information and exits.

-V n

Sets the verbosity bit-mask directly to n (where n is a decimal value between 0 and 65535). Meaning of the bits:

Prepared (Subject resp) ETHBAAT Jeno Balasko		No. 2/198 17-CRL 113 200/5 Uen		
Approved (Document resp) ETHLEL Elemer Lelik	Checked ETHGRY	Date 2015-05-15	Rev C	Reference

1: “NOT SUPPORTED” messages.

2: WARNING messages.

4: NOTIFY messages.

32 | 16 | 8: DEBUG messages. The debug-bits act like a 3-bit-length number, so the debug level has a value between 0 and 7. It is useful in case of abnormal program termination.

Note: When only parsing (option `-p`) DEBUG messages for ASN.1 values will appear in TTCN-3 form (e.x.: booleans will appear as `true` or `false`, instead of `TRUE` or `FALSE`).

Example: If you use the option `-v 6`, then all NOTIFY and WARNING messages will be printed, but the “NOT SUPPORTED” messages will be suppressed. To have the most detailed log, use the option `-v 63`. The default is `-v 7`.

`-w`

Suppresses all warning messages. Equivalent to `-v 4`.

`-x`

Disables the generation of TEXT encoder/decoder routines for all TTCN-3 types.

`-X`

Disables the generation of XER encoder/decoder routines for all TTCN-3 types.

`-y`

Disable subtype checking. Subtype information is parsed but ignored, there is no semantic check of the parsed subtype data.

`-Y`

Enforces legacy behaviour of the “out” function parameters (the “out” parameter will not be set to `<unbound>` at the start of the function , but will continue with the entry value).

`-z file`

Enables code coverage and profiling in the TTCN-3 files listed in the `file` argument. The TTCN-3 files in the list must be separated by spaces and must also appear among the compiler’s arguments.

Prepared (Subject resp) ETHBAAT Jenő Balasko		No. 2/198 17-CRL 113 200/5 Uen		
Approved (Document resp) ETHLEL Elemer Lelik	Checked ETHGRY	Date 2015-05-15	Rev C	Reference

-

The single dash character as command line argument has a special meaning: it controls the selective code generation. After the list of all TTCN-3 and ASN.1 modules a subset of these files can be given separated by a dash. This option instructs the compiler to parse all modules, perform the semantic analysis on the entire module hierarchy, but generate code only for those modules that are listed after the dash again. It is not allowed to specify a file name after the dash that was not present in the list before the dash. If the single dash is not present in the command line the compiler will generate code for all modules.

--ttn2json

Changes the purpose of the compiler to generate a JSON schema from the types defined in the specified TTCN-3 and ASN.1 modules. The parsing and semantic check of the input modules is still executed, but a JSON schema is generated instead of the C++ files. This must always be the first compiler option, and the previously listed options don't apply (apart from options `-A` and `-T`), instead the following options are available:

-j

Only types that have JSON coding enabled are included in the generated schema.

-f

Only types that have JSON encoding or decoding functions (or both) are validated by the schema.

- file

The single dash character as command line argument can be used to specify the name of the generated JSON schema file (it must be followed by exactly one argument, which is the file name). If it is not present, the schema file name is generated from the name of the first input file (the extension `".ttn"` or `".asn"` is replaced by `".json"`, or `".json"` is appended to the end of the file name if neither extension is present).

The meaning of options is also included in the manual page of the compiler. If your TTCN-3 installation is correct, the command `man compiler` will show you this manual page. If not, check the `MANPATH` environment variable.

## 6.1.2 Makefile Generator

You can generate the Makefile skeleton used for building the test suite using the program `ttn3_makefilegen`, which resides in the directory `$TTCN3_DIR/bin`. See section 2.3.1 of the TITAN User Guide [\[13\]](#) for details. The generated Makefile skeleton will use the parallel mode of the run-time environment by default. This can be overridden by using the option `-s` (see below).

Prepared (Subject resp) ETHBAAT Jeno Balasko		No. 2/198 17-CRL 113 200/5 Uen		
Approved (Document resp) ETHLEL Elemer Lelik	Checked ETHGRY	Date 2015-05-15	Rev C	Reference

The command line syntax of the makefile generator is the following:

```
usage: makefilegen [-abcdDfFgLImpRstTVwWXZ] [-K file] [-P dir] [-U none|type]
[-e ets_name] [-o dir|file]
[-t project_descriptor.tpd [-b buildconfig]] [-O file]
TTCN3_module[.ttn] ... ASN1_module[.asn] ... Testport_name[.cc] ...
```

or

```
makefilegen -v
```

The command line switches for generating Makefile(s) from Titan Project Descriptor (TPD) file(s) are not listed here, these are described in the next chapter.

The switches denoted by square brackets are optional. More than one option may be merged for abbreviation. For example, `-g -p` has exactly the same meaning as `-gp`. The following command line options are available (listed in alphabetical order):

`-a`

The flag refers to files using absolute path names in the generated Makefile. Makefile uses by default relative path names to access files located outside the current working directory of the compiler. Files from the current working directory are always referenced using only the file name without any directory. The flag generates a Makefile that is capable of using pre-compiled C++ and object files from central directories in order to save disk space and compilation time.

WARNING! This feature works only if the generated files of the central directory is kept up-to-date and all directories use exactly the same environment (platform, TTCN-3 Executor and C++ compiler version, etc.).

`-c`

Treat files not in the current directory as being in “central storage”. These files are assumed to be already built in their (separate) location.

`-d`

Dumps the data used for Makefile generation.

`-e <ETS name>`

Sets the name of the target binary program (i.e. the executable test suite) to `<ETS name>` in the generated Makefile. If this option is omitted, the name of the first TTCN-3 module will be used as default.

`-f`

Forces the makefile generator to overwrite the output Makefile. Without this flag the existing one will not be overwritten.

Prepared (Subject resp) ETHBAAT Jeno Balasko		No. 2/198 17-CRL 113 200/5 Uen		
Approved (Document resp) ETHLEL Elemer Lelik	Checked ETHGRY	Date 2015-05-15	Rev C	Reference

-g

Generates a Makefile that can be used with GNU `make` only. The resulting Makefile will be smaller and less redundant. It exploits the pattern substitution features of GNU `make`, which may cause syntax errors with other versions of `make`.

By default, Makefiles generated for GNU `make` use incrementally updated dependency files instead of `makefilegen`.

-K `file`

Enable code coverage for TTCN-3 modules listed in `file`. `file` is an ASCII text file which contains one file name per line. The set of files in `file` needs to be a subset of the TTCN-3 modules listed on the command line. (This parameter is simply passed to the TTCN-3 compiler through `COMPILER_FLAGS` in the Makefile.)

-l

Enable dynamic linking. All files of the project will be compiled with `-fPIC` and for each (static) object, a new shared object will be created. Then, these shared objects will be linked to the final executable instead of the (static) objects. It can be used to speed up the linking phase, in the price of somewhat lower performance and increased memory usage. It's recommended to use this flag only in the development phase of the project. Please note, that both the project's working directory (which holds the TITAN generated `.so` files) and the directory of TITAN libraries, most probably `${TTCN3_DIR}/lib`, should be appended to the `LD_LIBRARY_PATH` environment variable. Otherwise, the dynamic linker (or loader) won't be able to locate the shared objects required by the executable. This option is not supported on Windows (platform string `WIN32`).

-L

Create the makefile with `library` as the default target. The name of the generated library archive is `<ETS name>_lib.so` if the dynamic linking is enabled and `<ETS name>.a` otherwise.

-m

Always use `makedepend` for dependencies. By default, for makefiles used by GNU `make`, the compiler (usually GCC) is used to generate dependency information in an incremental fashion. This switch reverts to the process for generic make tools, which uses the `makedepend` tool.

Prepared (Subject resp) ETHBAAT Jeno Balasko		No. 2/198 17-CRL 113 200/5 Uen		
Approved (Document resp) ETHLEL Elemer Lelik	Checked ETHGRY	Date 2015-05-15	Rev C	Reference

-o <dir> | <file>

Writes the Makefile to the given directory or file. If the given argument is an existing directory, the generated Makefile will be placed into that directory. Otherwise, it is assumed to be the name of the generated Makefile. By default the file name is `Makefile`, placed in the current working directory.

-O <file>

Add file to the list of other files in the generated `Makefile` without analyzing the file contents and suffix. This option can be used to temporarily exclude some TTCN-3, ASN.1 modules ASN.1 or C++ files from the build process, but add them to the archive created by the command `make archive`.

-p

Generates `Makefile` with TTCN-3 preprocessing. All the TTCN-3 source files with the suffix `.ttcnpp` will be preprocessed using the C preprocessor. For details see section [11.3](#).

-R

Use function test runtime (TITAN\_RUNTIME\_2). Generates a Makefile that compiles and links the source code using the function test runtime.

-s

Generates a `Makefile` skeleton to be used with the single mode of the runtime environment. The only difference between the Makefiles for single and parallel modes is the setting of variable `$TTCN3_DIR` within them.

-U none|type

Generates a `Makefile` skeleton to be used with the chosen code splitting option. For details see the compiler options in 6.1.1.

-v

Prints version and license key information and exits.

-w

Suppresses all warning messages.

-Y

Enforces legacy behaviour of the “out” function parameters (the “out” parameter will not be set to `<unbound>` at the start of the function , but will continue with the entry value).

If any of the source (TTCN-3, ASN.1, user-written C++) files does not exist or cannot be accessed, `ttn3_makefilegen` exits with an error.

Other options are discussed in the next chapters.

Prepared (Subject resp) ETHBAAT Jeno Balasko		No. 2/198 17-CRL 113 200/5 Uen		
Approved (Document resp) ETHLEL Elemer Lelik	Checked ETHGRY	Date 2015-05-15	Rev C	Reference

### 6.1.3 Using the Makefile Generator to Generate Makefile(s) from Titan Project Descriptor file(s)

It is possible to generate Makefile(s) from command line using the Titan Project Descriptor file(s) (TPD) generated by the Eclipse plugin. The Eclipse plugin generates a TPD file for each project. This file contains all the information needed to generate a Makefile for that project. See reference [17] for details.

The makefile generator validates the TPD file with a schema file which is located at `${TTCN3_DIR}/etc/xsd/TPD.xsd`. If there are validation errors or the xsd file cannot be found some warnings will be displayed, this validation can be disabled with the '-V' option. Validation errors will not prevent the generation of makefiles and symlinks, however if there are such warnings it is strongly recommended to check the TPD files for errors because these errors may cause either other errors during the generation of the makefiles and symlinks or the creation of invalid makefiles and symlinks.

Projects can reference other projects. These dependencies between projects are contained by the generated TPD files. The TPD file is placed in the project root directory. Every project has also a working directory (usually named 'bin') which is relative to the project root directory. The working directory will contain symlinks to all the source files contained by the project and the files generated when building the project. The TPD file of the project contains the names and relative paths of all the projects that the project depends on, therefore the relative location of these projects must not be changed or these won't be found. For large projects the TPD files will describe a project hierarchy that is not necessarily a tree structure, for example:

The command line makefile generator can process the TPD file hierarchy generated by Eclipse and generate one or more Makefiles for these. There are three methods to generate Makefiles:

- 1 Generate a single Makefile that will contain all files from all projects. The following command line options can be used for this: `-t -b -D -P -V -W`.

Prepared (Subject resp) ETHBAAT Jeno Balasko		No. 2/198 17-CRL 113 200/5 Uen		
Approved (Document resp) ETHLEL Elemer Lelik	Checked ETHGRY	Date 2015-05-15	Rev C	Reference

When using this method the `-c` switch should not be used because in this case all the files are seen as part of one large project.

- 2 Generate a Makefile hierarchy recursively (`-r`): for each TPD file generate a Makefile that builds only one project but has a dependency on other projects using the feature called “central storage”. This dependency relation in the Makefile means that prior to building a project all the other projects that it depends on must be built. The dependency relation is contained by the top-level project’s Makefile. For that to work the central storage (`-c` switch in the makefile generator) feature is used to avoid compiling the source files also in top level projects that have already been compiled in the sub-projects where they belong to. Using this one Makefile all the projects can be built in the proper order. The following command line options can be used for this: `-t -b -D -P -F -T -X -V -W -Z -H`.
- 3 Generate a Makefile hierarchy with improved linking method (`-Z`): for each TPD file generate a Makefile that builds only one project but has a dependency on other projects. It provides highly flexible way of linking static- and/or dynamic libraries together. The following command line options are obligatory `-t -Z -F -r` and these are optional: `-H -W`.

When generating multiple Makefiles the working directories of each referenced project are determined by the TPD file of the project. The TPD file can contain more than one build configuration, but there’s always one active configuration. The active configuration is determined by the TPD file itself by the element `<ActiveConfiguration>`. Different build configurations can have different working directories and other settings. This can be overruled by the referencing project’s required configuration setting (via `<requiredConfiguration>` embedded into `<configurationRequirement>`) or in case of a top-level TPD by using the `-b` command line option. Both the Makefile and the symlinks to source files are generated into the working directory.

If there is no “workingDirectory” specified in the TPD file, default directory will be created with name “bin”. If more than one project define the same directory for working directory a collision can happen. This can be avoided by the command line switch `-W` (see below).

If you want to generate Makefiles from tpd files with incremental dependency (via `.d` files), you shall apply switch `-g` and you must not apply `-m`, in addition to these the top level project descriptor (tpd) file shall contain the element ordering incremental dependency as follows:

```
<incrementalDependencyRefresh>
true
</incrementalDependencyRefresh>
```

The following TPD related command line options are available:

Prepared (Subject resp) ETHBAAT Jeno Balasko		No. 2/198 17-CRL 113 200/5 Uen		
Approved (Document resp) ETHLEL Elemer Lelik	Checked ETHGRY	Date 2015-05-15	Rev C	Reference

`-t filename.tpd [-b buildconfig]`

Use the supplied Titan Project Descriptor file to generate the Makefile. Information about directories, files and certain options is extracted from the TPD file and used to generate the Makefile(s). Additional files can be specified on the command line. Options from the command line override any option specified in the TPD file. If hierarchical makefilegen is ordered (`-Frcg` or `-FrcgWp`) then the immediately referred projects will be generated according to the element `<requiredConfiguration>` of the ordered top level active configuration. This is applied recursively.

`-b buildconfig`

On top level use the specified build config instead of the default active configuration defined in the TPD.

`-r`

Generate a Makefile hierarchy recursively from TPD hierarchy.

`-P <dir>`

Print out a file list found in a given TPD and optionally in its referenced TPDs to `stdout`, relative to the given directory `<dir>`. It requires the `-t` option and a valid directory as its parameter. If used together with the `-a` option the list will contain absolute paths and the directory parameter will not be taken into account.

`-V`

Disable validation of TPD file with the TPD.xsd schema file

`-F`

Force the makefile generator to overwrite all output Makefiles. Without this flag the existing files in the Makefile hierarchy will not be overwritten.

`-T`

Generate only the top-level Makefile of the hierarchy.

`-X`

Generate an XML file that describes the project hierarchy as seen by the makefile generator.

`-D`

Use current directory as working directory. Note! This flag overrides the working directory coming from the TPD. In case of Generate Makefile hierarchy recursively (`-r`) flag, `-D` flag is valid only for top level project.

`-W`

Prepared (Subject resp) ETHBAAT Jenö Balasko		No. 2/198 17-CRL 113 200/5 Uen		
Approved (Document resp) ETHLEL Elemer Lelik	Checked ETHGRY	Date 2015-05-15	Rev C	Reference

Prefix working directories with project name. This is needed if more than one TPD file is in the same directory, because this directory will then be the root of more than one project. The working directories (usually 'bin') will conflict, by using `-W` the working directory name will be prefixed by the project name, for example 'MyProject\_bin'.

Please note that in case of incorrect TPD files, the errors are displayed multiple times if the faulty TPD is included more than once in the project structure.

`-Z`

Use the improved linking method. It generates a flexible hierarchy of static and dynamic libraries. Each project can be set to build a static or dynamic library or an executable too.

`-H`

Use hierarchical project generation. Use it with `-Z` option. It provides makefiles for generating hierarchical binaries without flattening the project hierarchy. `make` can be called in any working directory, the lower level projects will be handled properly. All project can be regarded as top level project. Execution time of `make` is higher than in case of applying `-Z` without `-H`. (The difference is 50-100% for top level modification, 0-10% for lower level modification.)

#### Examples:

1. Hierarchical makefile filegeneration from the directory of the top level project:

```
makefilegen -FrcgWp -t MyTopLevelProj.tpd
```

2. Project hierarchy file generation:

```
makefilegen -rcX -t MyTopLevelProj.tpd
```

3. Hierarchical makefile filegeneration from the directory of the top level project:

```
makefilegen -FWrZH -t MyTopLevelProj.tpd
```

#### 6.1.3.1 Using the improved linking method (`-Z` and `-H` option)

Node `<ReferencedProjects>` contains the projects whose `<defaultTarget>` is either a library (static or dynamic) or an executable. See the XML excerpt.

Prepared (Subject resp) ETHBAAT Jenő Balasko		No. 2/198 17-CRL 113 200/5 Uen		
Approved (Document resp) ETHLEL Elemer Lelik	Checked ETHGRY	Date 2015-05-15	Rev C	Reference

```

<ReferencedProjects>
  <ReferencedProject name="refProj1"
projectLocationURI="../../workspace/refProjDir1/refProj1.tpd"/>
  <ReferencedProject name="refProj2"
projectLocationURI="../../workspace/refProjDir2/refProj2.tpd"/>
</ReferencedProjects>
<MakefileSettings>
  <GNUmake>true</GNUmake>
  <incrementalDependencyRefresh>true</incrementalDependencyRefresh>
  <dynamicLinking>true</dynamicLinking>
  <defaultTarget>library</defaultTarget>
  <targetExecutable>bin/yourexecutable</targetExecutable>
  <linkerLibraries>
    <listItem>externallib1</listItem>
  </linkerLibraries>
  <linkerLibrarySearchPath>
    <listItem>${externallib}/lib</listItem>
  </linkerLibrarySearchPath>
</MakefileSettings>

```

“refProj1” and “refProj2” are subprojects of the actual one. Other info about these subprojects can only be obtained in their own TPD file.

<incrementalDependencyRefresh> is set to true in the project structure. <GNUmake> shall be set to true. In this scope other tools are not supported. The node <dynamicLinking> true sets the dynamic linking method for the actual project. The node <defaultTarget> indicates whether the output is a library. If it is omitted the output is an executable.

<linkerLibrarySearchPath> and <linkerLibraries> provide information about third party (not in the project hierarchy) libraries.

The solution is based on the following corner stones:

Static and dynamic libraries can only be linked on <defaultTarget> executable build level. This means that a <defaultTarget> library cannot be generated by mixing other static and dynamic libraries.

A <defaultTarget> library with dynamic linking can be generated only from its own project’s object file(s) and subprojects dynamic libraries.

Static libraries are so called thin archives. This means that a static library is generated from own projects’s object file(s) and contains links to object files of other thin archive(s).

Third party libraries (e.g.: Linux core libs, openssl) can only be linked dynamically.

If the <defaultTarget> is library and <dynamicLinking> is true, the following aspects are to be considered:

Prepared (Subject resp) ETHBAAT Jeno Balasko		No. 2/198 17-CRL 113 200/5 Uen		
Approved (Document resp) ETHLEL Elemer Lelik	Checked ETHGRY	Date 2015-05-15	Rev C	Reference

it can be linked together with another dynamic library  
it cannot be linked together with a static library  
it can be linked together with a third party dynamic library (e.g. openssl)  
it cannot have subproject(s) with `<defaultTarget>` is executable

Position dependent code cannot be linked with position independent code. This is a known limitation of the GNU linker. The third party libraries shall be added to `LD_LIBRARY_PATH`, or be copied to a directory contained by the `LD_LIBRARY_PATH`

If the `<defaultTarget>` is library and `<dynamicLinking>` is false, the following aspects are to be considered:

it can be linked together with another static library  
it cannot be linked together with a dynamic library  
it cannot be linked together with a third party static library<sup>18</sup> (e.g. openssl)  
it can have subproject(s) with `<defaultTarget>` is executable

If the project's `<defaultTarget>` is an executable, then the static and dynamic libraries can be linked together. If on a lower level project there is reason to link static and dynamic libraries together, then the node `<defaultTarget>` shall be set to executable, too. If `-H` option is NOT set then NO executable file will be generated for lower level projects. In this case the Makefile will generate only objects. The top-level project's `<defaultTarget>` shall be set to executable. This is not checked if the `-H` option is set, since it causes every node to behave as if it were the top-level node.

**Important:** within a Project hierarchy if the real top-level project with `<defaultTarget>` executable is set to `<dynamicLinking>` true, then every sublevel project with `<defaultTarget>` executable shall be set to `<dynamicLinking>` true as well. A top-level project with `<defaultTarget>` executable and `<dynamicLinking>` false has no such constraint. If the above requirements are not fulfilled it results in a linker error.

The makefile uses the linker flag `-rpath`, so there is no need to set the environment variable `LD_LIBRARY_PATH` for the libraries in the project hierarchy.

If option `-H` is used:

There is a new make command in the makefile that is generated by using the `H` flag. The call of **make clean-all** cleans the whole hierarchy, whereas the behavior of **make clean** changed, it only cleans the actual project.

If option `-H` is not used: In a cleaned Makefile structure the **make** shall be called in the working directory of the top-level project.

<sup>18</sup> Not supported

Prepared (Subject resp) ETHBAAT Jeno Balasko		No. 2/198 17-CRL 113 200/5 Uen		
Approved (Document resp) ETHLEL Elemer Lelik	Checked ETHGRY	Date 2015-05-15	Rev C	Reference

The optimal TPD for hierarchical structure (-H option)

The following picture shows a simple Project structure:

The arrows show the Project references. T1 has two `<ReferencedProjects>` nodes in the TPD: M1 and M2. M1 has three: S1, S2 and S3, and so on. Since the structure is hierarchical S2 will be iterated twice. M1-S2 dependencies make S2 be compiled and linked. The makefile of M2 only knows about the project S2. If the code for M2 is generated, the iteration of S2 is inevitable, even if the make of M1 had generated the code. This cannot be avoided and increases the run time of T1's make. But relations like T1-S3 (red arrow) should be omitted since they are unnecessary and avoidable. T1 does not need to iterate S3 since M1 did it before and T1 can reach it via M1. Summarized: Try to minimize the loops in the project hierarchy graph. In big hierarchies (50-100 Projects) a well organized structure can have an overhead of up to 50%-100%. A poorly organized one can run even 5 times longer than the flat hierarchy (without -H option).

Rewriting an existing hierarchy can lead to linker errors. For example: an error message beginning with *"undefined reference to..."* means that one (or more) project(s) is/are missing from the calling one.

#### Usage hints:

- 1 Hierarchical building can be applied by option -Z.
- 2 Any project can be regarded as top level project if the makefiles are generated with the additional option -H.

Prepared (Subject resp) ETHBAAT Jeno Balasko		No. 2/198 17-CRL 113 200/5 Uen		
Approved (Document resp) ETHLEL Elemer Lelik	Checked ETHGRY	Date 2015-05-15	Rev C	Reference

- 3 Remove unnecessary references. It can dramatically decrease the hierarchical build time.
- 4 To optimize the building time, work only on the highest level project(s). They should be set for executable, all lower level and all unused branches should be set for library, especially for dynamically linked library. Take into account that it is not the best solution for the the final executable because the dynamically linking libraries can decrease the speed of running.

#### 6.1.3.2 Placing custom rules and new targets into the generated Makefile

Custom rules and new targets can be inserted into the generated Makefile. This feature consists of two parts: calling a script whose output will be inserted into the generated Makefile and specifying new targets in the TPD file which will be inserted into the generated Makefile to the appropriate places. These two parts can be used together to accomplish the desired solution. The script shall print the project's custom Makefile rules to its standard output.

These rules have targets such as:

```
customtarget : dependency1 dependency2
               <command1>
               <command2>
```

The second part of the feature is to add these custom targets to other specified places of the Makefile. Currently these places are: PHONY, TTCN3\_MODULES, TTCN3\_PP\_MODULES, TTCN3\_INCLUDES, ASN1\_MODULES, USER\_SOURCES, USER\_HEADERS, USER\_OBJECTS, OTHER\_FILES. These places usually contain a list of files which will be used in the build process at different stages. By adding a new custom target to one or more of these places it becomes part of the dependency tree which will be processed by the make program and our new custom rule will be automatically invoked when necessary.

Prepared (Subject resp) ETHBAAT Jeno Balasko		No. 2/198 17-CRL 113 200/5 Uen		
Approved (Document resp) ETHLEL Elemer Lelik	Checked ETHGRY	Date 2015-05-15	Rev C	Reference

An example of how to print some message when make is done with the “all” target:

First make a script that prints the rule itself (here a python script):

```
print """
buildwithmessage: all
                @echo 'Here i built the project for you!!!'
"""
```

Next add the new rule to the appropriate place, in this case to the PHONY targets because it's not a real file to be created.

The script invocation and the addition of the new target are specified in the TPD file inside the MakefileSettings element (after the buildLevel element):

```
<ProjectSpecificRulesGenerator>
  <GeneratorCommand>python
  MyRulesAdder.py</GeneratorCommand>
  <Targets>
    <Target name=" buildwithmessage" placement="PHONY"/>
  </Targets>
</ProjectSpecificRulesGenerator>
```

To see the message after the build make shall be invoked with the new target:  
make buildwithmessage

Of course in most cases real files are generated and not phony targets. These can be ttcn files generated from some type descriptions written in other notations or languages. Or cc/hh files generated by lexer and parser generators (flex/bison). In these cases the generated file name shall be the custom target and it shall be added to places like TTCN3\_MODULES or USER\_SOURCES. This way when the make program encounters a rule that depends on the new target (for example our new custom ttcn-3 source file) it will use our added custom rule and the <command> part of that rule will create/update the ttcn-3 file before it will be used by the TITAN compiler to generate cc/hh files and then object file and finally the executable.

This method of making changes on the generated Makefile is preferred over the legacy makefile modifier scripts method. The makefile modifier scripts are error prone because these contain many assumptions about the exact content of the Makefile which may not be true for future versions of the makefile generator.

### 6.1.3.3 External directory usage in tpd

External directory usage is described with OSS\_DIR example.

To enable proper OSS usage, some parameters must be set in the tpd file. Lower extractions from tpd file can be seen, details which are useful for setting up OSS usage.

```
<Files>
  <FileResource projectRelativePath="OSS_H323_MESSAGES.c"
  relativeURI="src/OSS_H323_MESSAGES.c"/>
```

Prepared (Subject resp) ETHBAAT Jenő Balasko		No. 2/198 17-CRL 113 200/5 Uen		
Approved (Document resp) ETHLEL Elemer Lelik	Checked ETHGRY	Date 2015-05-15	Rev C	Reference

```
<FileResource projectRelativePath="OSS_H323_MESSAGES.h"
relativeURI="src/OSS_H323_MESSAGES.h"/>
<FileResource projectRelativePath="OSS_H323_MESSAGES_linux.c"
relativeURI="src/OSS_H323_MESSAGES_linux.c"/>
</Files>

<ActiveConfiguration>Default</ActiveConfiguration>
<Configurations>
  <Configuration name="Default">
    <ProjectProperties>
      <MakefileSettings>
        <preprocessorIncludes>
          <listItem>[OSS_DIR]/include</listItem>
        </preprocessorIncludes>
        <linkerLibrarySearchPath>
          <listItem>[OSS_DIR]/lib</listItem>
        </linkerLibrarySearchPath>
      </MakefileSettings>
    </ProjectProperties>
  </Configuration>
</Configurations>
```

Please note that OSS\_DIR system variable needs to be set properly in your path.

NOTE: using makefile updater scripts are obsolete.

## 6.2 The Compilation Process for TTCN-3 and ASN.1 Modules

Before analyzing the input modules the compiler applies some heuristics for each source file to determine whether it contains a TTCN-3 or ASN.1 module. These so-called pre-parsing algorithms consider only the first few words of the files so it can happen that the compiler is unable to recognize its input and stops immediately with an error message. This is the case, for example, if the beginning of the module is either erroneous or contains strange and misleading comments. In this case using the command-line options `-T` and `-A` you can bypass the pre-parsers and force to interpret the corresponding file as a TTCN-3 or ASN.1 module, respectively.

During its run, the compiler reports its activities on its standard error stream like the following. The level of detail for these messages can be controlled with the flag `-V`.

```
Notify: Parsing TTCN-3 module 'MyModule.ttcn'...
Notify: Parsing ASN.1 module 'MyAsnModule.asn'...
Notify: Checking modules...
Notify: Generating code...
Notify: File 'MyModule.hh' updated.
Notify: File 'MyModule.cc' updated.
Notify: File 'MyAsnModule.hh' updated.
Notify: File 'MyAsnModule.cc' updated.
Notify: 4 files updated.
```

Prepared (Subject resp) ETHBAAT Jeno Balasko		No. 2/198 17-CRL 113 200/5 Uen		
Approved (Document resp) ETHLEL Elemer Lelik	Checked ETHGRY	Date 2015-05-15	Rev C	Reference

First, the compiler reads the TTCN-3 and ASN.1 input files and performs syntax check according to the BNF of TTCN-3 [\[1\]](#) (including the additions of [\[3\]](#)) or ASN.1 [\[4\]](#) [\[7\]](#) [\[8\]](#) [\[9\]](#). The syntax errors are reported with the appropriate line number. Whenever it is possible, the compiler tries to recover from syntax errors and continue the analysis in order to detect further errors. Please note that error recovery is not always successful and it might result in additional undesired error messages when the parser gets out of synchronization. Therefore it is recommended to study the first lines on the compiler's error listings because the error messages at the end are not always relevant.

After the syntax check the compiler performs semantic analysis on TTCN-3 /ASN.1 module(s) and verifies whether the various definitions and language elements are used in the appropriate way according to the static semantics of TTCN-3 and ASN.1 languages. In addition to error messages the compiler reports a warning when the corresponding definition is correct, but it might have unwanted effects.

If both syntax and semantic checks were successful, the compiler generates a C++ header and source file that contains the translated module. If the name of the input module is `MyModule` (i.e. it begins with `module MyModule`), the name of the generated header and source file will be `MyModule.hh` and `MyModule.cc`, respectively. Note that the name of the output file does NOT depend on the name of input file. In ASN.1 module names the hyphens are converted to underscore characters (e.g. the C++ code for `My-Asn-Module` will be placed into `My_Asn_Module.hh` and `My_Asn_Module.cc`).

By default, the compiler generates the C++ code for all input modules. This can be unnecessarily time-consuming when doing incremental builds for large projects. The build process can be significantly speed up if the compiler option `-` (single dash) is used. In this case the C++ code will be generated only for those modules that have changed since last build of the ASN.1 modules. With selective code generation it can be exploited that the make utility can easily tell which source files were changed since the last compilation.

This sophisticated command line syntax is necessary because in general case it is impossible to perform the semantic analysis on a subset of the modules because those may import from modules outside the list. Moreover, to avoid undesirable side-effects of the code optimization techniques implemented in the compiler (e.g. type and value folding) the C++ code is generated not only for the modified modules, but for all modules that import definitions (either directly or indirectly) from the modified ones.

When the compiler translates an ASN.1 module, the different ASN.1 types are mapped to TTCN-3 types as described in the table below.

*Table 11 Mapping of ASN.1 types to TTCN-3 types*

ASN.1	TTCN-3
Simple types

§ BMPString, UniversalString, UTF8String

## 6.3 Particularities of ASN.1 Modules

This section describes the checks the compiler performs on ASN.1 modules.

### 6.3.1 Type Assignments

In this first phase only basic checks are made: the compiler checks for unresolved and for circular references. The simplest example for circular reference is the following:

```
T1 ::= T2
T2 ::= T1
```

But there are more complex cases, especially related to non-optional fields of compound types. For example, X.680 clause 47.8.1 contains an illegal type definition:

```
A ::= SET {
  a A,
  b CHOICE {
```

Prepared (Subject resp) ETHBAAT Jeno Balasko		No. 2/198 17-CRL 113 200/5 Uen		
Approved (Document resp) ETHLEL Elemer Lelik	Checked ETHGRY	Date 2015-05-15	Rev C	Reference

```

        c C,
        d D,
        ...
    }
}

```

It is easy to see that one can not assign a (finite) value to a variable of type `A`: there is an endless recursion because of the field `a`, which is the same type as the parent-type. If this field were optional, then the recursion could be broken at any level.

### 6.3.2 Value Assignments

The compiler checks the unresolved/circular references also in case of value assignments.

The value is checked according to the type:

`NULL`: Only the `NULL` value is accepted.

`BOOLEAN`: `TRUE` or `FALSE` value is accepted.

`BIT STRING`: You can use `hstring`, `bstring` or (even empty) set of named bits. In the latter case, the compiler checks if there are bits with the given names.

`OCTET STRING`: Only `hstring` or `bstring` form is accepted.

`character strings`: The `cstring`, `tuple`, `quadruple` form and the combination of these forms (`CharacterStringList`) are accepted.

`INTEGER`: Number form and named values (defined in the type with which the value is associated) can be used.

`REAL`: You can use the special values (`0`, `PLUS-INFINITY`, `MINUS-INFINITY`) as well as the associated `SEQUENCE` type (defined in X.680 clause 20.5) and the real number form (defined in X.680 clause 11.9).

`OBJECT IDENTIFIER`: All possible notations (i.e. `NameForm`, `NumberForm`, `NameAndNumberForm` and `DefinedValue`) can be used for the components. The predefined names given in Annex A-C of X.660 are recognized for the first two or three components. According to X.680 clause 31 it is checked whether the `Number` and `DefinedValue` is (a reference to) a non-negative integer or `OBJECT IDENTIFIER/RELATIVE-OID` value, respectively. If `NameAndNumberForm` is used, only the number is considered for the code generation. A warning message is displayed if in the first two components the given name and number is not in accordance with each other.

`ENUMERATED`: Only the identifiers defined in the corresponding type can be used.

Prepared (Subject resp) ETHBAAT Jeno Balasko		No. 2/198 17-CRL 113 200/5 Uen		
Approved (Document resp) ETHLEL Elemer Lelik	Checked ETHGRY	Date 2015-05-15	Rev C	Reference

**CHOICE:** The compiler checks if there is an alternative with the given name, then checks if the value corresponds to the type of the selected alternative.

**SEQUENCE OF and SET OF:** You can use the “empty” value (`{ }`) or list of values separated by commas, enclosed in braces. Each value in the list is checked.

**SEQUENCE:** The values of the fields shall be in the same order as in the corresponding type definition. Components marked with `OPTIONAL` or `DEFAULT` can be skipped. The components are checked recursively.

**SET:** There shall be one and exactly one value definition for each not `OPTIONAL` or `DEFAULT` component defined in the corresponding type. They can appear in any order.

Named values (in case of `INTEGER` and `ENUMERATED`) have higher priority than defined values.

### 6.3.3 Type Definitions

The compiler makes an exhaustive check of the types defined in the module. For the different types, the following checks are executed:

**tagged types:** As you can use value references in the tags, the compiler checks if the value is a non-negative integer.

**BIT STRING:** When using named bits, the bit number must be a non-negative integer. Each bit can have only one identifier (duplications are not permitted).

**INTEGER:** Value references in named numbers (if any) must reference integer values.

**ENUMERATED:** Value references (if any) must reference integer values. The compiler assigns a number<sup>19</sup> for each item which does not have an associated number. Duplicated values (neither in identifiers, nor in associated number values) are not permitted. Items defined after an ellipsis must have associated numbers that increase monotonously. For details, see X.680 clause 19.

**CHOICE:** Every alternative must have different tag. Tags in the extension must increase monotonously (X.680 28.4). (The canonical order of tags is defined in X.680 8.4.)

<sup>19</sup> According to X.680 clause 19.3

Prepared (Subject resp) ETHBAAT Jeno Balasko		No. 2/198 17-CRL 113 200/5 Uen		
Approved (Document resp) ETHLEL Elemer Lelik	Checked ETHGRY	Date 2015-05-15	Rev C	Reference

**SEQUENCE:** The tags in optional groups<sup>20</sup> must have different tags (X.680 24.5).

All tags in the extension must be distinct from tags used in the first optional group after the second ellipsis (X.680 24.6).

**SET:** The types used in a **SET** type shall all have different tags (X.680 26.3). Tags in the extension must increase monotonously.

Extension is not always permissible in **CHOICE**, **SEQUENCE** and **SET** (see X.680 47.7).

Here is an example:

```
illegal-type ::= SET {
  a INTEGER,
  b CHOICE {
    c C,
    d D,
    ...,
    ...
  },
  ...,
  e E
}
```

The problem is that the (BER) decoder of a version 1 system cannot attribute an unknown element (received from a version 2 system) unambiguously to a specific insertion point.

## 6.4 Using Component Relation Constraints from TTCN-3

To handle constructs defined in X.681, X.682 and X.683 is not easy from TTCN-3. There is an ETSI technical report<sup>21</sup> which describes how to transform these constructs to equivalent X.680 constructs. The clause 4.4 of this document is about transforming information objects.

“The transformation rules presented in this clause cannot reproduce the full semantics of the information objects they replace. The transformation rules cannot preserve component relation constraints. These constraints provide the ability to constrain a type or value with reference to a different field within an information object set.”

This is not such a great problem, because BER does not “see” the constraints. But there is a situation when the transformations are unusable: when references to information object type fields are constrained by component relation constraints. Let’s take the example from X.682, clause 10 (with a little bit of modifications, to enlighten the problem):

<sup>20</sup> Optional group: One or more consecutive occurrences of **OPTIONAL** or **DEFAULT** fields, including the first not **OPTIONAL** or **DEFAULT** field.

<sup>21</sup> TR 101 295

Prepared (Subject resp) ETHBAAT Jeno Balasko		No. 2/198 17-CRL 113 200/5 Uen		
Approved (Document resp) ETHLEL Elemer Lelik	Checked ETHGRY	Date 2015-05-15	Rev C	Reference

```
ERROR-CLASS ::= CLASS
{
    &category PrintableString(SIZE(1)),
    &code INTEGER,
    &Type
}
WITH SYNTAX {&category &code &Type}

ErrorType1 ::= [1] INTEGER
ErrorType2 ::= [1] REAL
ErrorType3 ::= [1] CHARACTER STRING
ErrorType4 ::= [1] GeneralString

ErrorSet ERROR-CLASS ::=
{
    {"A" 1 ErrorType1} |
    {"A" 2 ErrorType2} |
    {"B" 1 ErrorType3} |
    {"B" 2 ErrorType4}
}

ErrorReturn ::= SEQUENCE
{
    errorCategory ERROR-CLASS.&category ({ErrorSet}) OPTIONAL,
    errors SEQUENCE OF SEQUENCE
    {
        errorCode ERROR-CLASS.&code ({ErrorSet}{@errorCategory}),
        errorInfo ERROR-CLASS.&Type ({ErrorSet}{@errorCategory,@.errorCode})
    } OPTIONAL
}
```

After applying the transformation rules described in ETSI technical report, the equivalent definitions look like this:

```
ErrorReturn ::= SEQUENCE
{
    errorCategory PrintableString(SIZE(1)) OPTIONAL,
    errors SEQUENCE OF SEQUENCE
    {
        errorCode INTEGER,
        errorInfo CHOICE
        {
            errorType1 ErrorType1,
            errorType2 ErrorType2,
            errorType3 ErrorType3,
            errorType4 ErrorType4
        }
    } OPTIONAL
}
```

It is plainly seen that this is not a legal type definition: the alternatives of a CHOICE must have distinct tags. The original definition is unambiguous, because the `errorCode` component “tells” the decoder how to interpret the `errorInfo` component.

Prepared (Subject resp) ETHBAAT Jeno Balasko		No. 2/198 17-CRL 113 200/5 Uen

## 7 The Run-time Configuration File

The behavior of the executable test program is described in the run-time configuration file. This is a simple text file, which contains various sections. The usual suffix of configuration files is `.cfg`.

Each section begins with a section name within square brackets. Different sections use different syntax, thus the section name determines the possible syntax of the members.

The configuration file can contain any white space characters. There are three ways to put comments in the file: you can use the C comment delimiters (i.e. `/*` and `*/`). Additionally, characters beginning with `#` or `//` are treated as comments until the end of line.

Character string values shall be given between quotation marks. The non-printable characters as well as the quotation mark character within string values must be escaped using TTCN-3 or C escape sequences or quadruple notation. All kinds of escape sequences that are available in TTCN-3 and C languages (including octal and hexadecimal notation) are recognized.

All sections are optional, thus an empty file is also a valid (but meaningless) configuration file. The sections are processed in the given order. In case of duplicated sections, all sections will be processed and no warnings will be issued.

In the following we present all possible sections of the configuration file. The majority of sections are applicable in both single and parallel modes with identical meaning. However, some sections or settings in a section are applicable either in single or parallel mode only.

The indication (Parallel mode) following the section title signals that the concerned section is processed in parallel operation mode only. Irrelevant sections or options are ignored in each mode and a warning message is displayed during configuration file processing. For details on running TITAN TTCN-3 test suites in either single or parallel mode using see the TITAN TTCN-3 User Guide (see [\[13\]](#)).

The component name defined by the `create` operation (see [4.5]) can contain any characters. This component name can be used without quoted marks but it shall be used with quoted marks (i.e. as quoted string) if it contains extra characters e.g. space (" "), hyphen ("-") or dot ("."). See also the examples of this chapter in sections [MODULE\_PARAMETERS] and [TESTPORT\_PARAMETERS].

Prepared (Subject resp) ETHBAAT Jeno Balasko		No. 2/198 17-CRL 113 200/5 Uen

## 7.1 [MODULE\_PARAMETERS]

This section shall contain the values of all parameters that are defined in your TTCN-3 modules. One does not have to separate the parameters for each TTCN-3 module as their name identifies them uniquely.

The parameters shall be specified after each other in any order. Each parameter must be given in the following order: module name (optional)<sup>22</sup>, parameter name, field names (in case of records, sets or unions; optional) or array indexes (in case of arrays, records of or sets of; optional), assignment or concatenation operator (that is, the characters := or &=) and parameter value. An optional terminator semicolon may be used after each parameter value. The concatenation operator can be applied to list types (record of, set of). In this case only the value list notation can be used.

### 7.1.1 BNF Productions for this Section<sup>23</sup>

```

ModuleParametersSection ::= "[MODULE_PARAMETERS]" {ModuleParameter}

                | "{" FieldValue {"," FieldValue} "}"
                | "{" ArrayItem {"," ArrayItem} "}"
                | "{" IndexItem {"," IndexItem} "}"
                | "(" ParameterValue {"," ParameterValue} ")"
                | ("complement" | "superset" | "subset") "(" ParameterValue {","
ParameterValue} ")"
FieldValue ::= FieldName ":" ParameterValueOrNotUsedSymbol
FieldName ::= Identifier | ASNI LowerIdentifier
ArrayItem ::= ParameterValueOrNotUsedSymbol | ("permutation" "(" ParameterValue
{"," ParameterValue} ")")
IndexItem ::= "[" IntegerValue "]" ":" ParameterValue
ParameterValueOrNotUsedSymbol ::= ParameterValue | "-"

```

The parameter value can be one of the followings:

- a Integer value. A number in decimal notation or an expression composed of numbers using the basic arithmetic operations to allow more flexibility with macro substitution.
- b Floating point value. A floating point number in decimal dot notation or exponential notation or an arithmetic expression composed of such values.
- c Bitstring value (in the notation of TTCN-3). String fragments can be concatenated to allow more flexible macro substitution.
- d Hexstring value (in the notation of TTCN-3). String fragments can be concatenated to allow more flexible macro substitution.
- e Octetstring value (in the notation of TTCN-3). String fragments can be concatenated to allow more flexible macro substitution.
- f Charstring value (between quotation marks; escape sequences are allowed). String fragments can be concatenated to allow more flexible macro substitution.
- g Universal charstring value (sequence of concatenated fragments; each fragment can be either a printable string within quotation marks or a quadruple in TTCN-3 notation).
- h Boolean value (`true` or `false`).
- i Object identifier (`objid`) value (in the notation of TTCN-3 ). Only `NumberForm` or `NameAndNumberForm` notations are allowed.
- j Verdict value (`none`, `pass`, `inconc`, `fail` or `error`).
- k Enumerated value (the symbolic value, i.e. an identifier). Numeric values are not allowed.
- l Omit value (i.e. `omit`). Valid for optional record or set fields only.

Prepared (Subject resp) ETHBAAT Jeno Balasko		No. 2/198 17-CRL 113 200/5 Uen		
Approved (Document resp) ETHLEL Elemer Lelik	Checked ETHGRY	Date 2015-05-15	Rev C	Reference

- m `null` value for TTCN–3 component and default references.
- n `NULL` value for the ASN.1 `NULL` type.
- o “?” value: AnyValue for matching
- p “\*” value: AnyValueOrNone for matching
- q IntegerRange/FloatRange/StringRange: matching an integer/float/charstring range
- r Pattern for pattern matching in charstring and universal charstring
- s Bit/Hex/Octet –string matching mechanism which are bit/hex/octet strings that contain “?” and “\*” for matching
- t “mtc” and “system” values for component references
- u Compound value with assignment notation. One or more fields (separated by commas) with field names within brackets for types `record` and `set`.
- v Compound value with value list notation. Comma separated list of values between brackets for types `record of`, `set of` and `array`.
- w Compound value with indexed list notation. One or more fields with field index and value for types `record of` and `set of`
- x Compound value containing a template list. Can be a value list, complemented value list, superset and subset list.

Nested compound values are permitted in arbitrary depth. In compound values with assignment and value list notations the “-” symbol can be used to skip an element. In value list notation for `record of` and `set of` permutation lists can be used.

### 7.1.2 Differences between the TTCN-3 and the Configuration File Module Parameters Section Syntax

Neither the `ttcn-3` syntax nor the module parameter section syntax is the subset of the other. Historically some module parameter values that are not legal in `ttcn-3` have been accepted, for backward compatibility reasons this behavior has been kept. In most cases the module parameter syntax is a subset of the `ttcn-3` syntax but there are important exceptions:

- Field values of records and sets can be referenced multiple times, in this case all field value assignments will be executed in order of appearance. Example: `mp_myRecord := { a :=1, b:=3, a:=2 } // a==2`

Prepared (Subject resp) ETHBAAT Jeno Balasko		No. 2/198 17-CRL 113 200/5 Uen		
Approved (Document resp) ETHLEL Elemer Lelik	Checked ETHGRY	Date 2015-05-15	Rev C	Reference

- In an assignment notation used for a union multiple field values can appear, only the last value will be used. Example: `mp_myUnion := { a:=1,b:=2,a:=3 }` only `a:=3` will be used, the other 2 assignments are disregarded without warnings.
- The order of fields in assignment notation for records does not have to be identical to the order of fields specified in the type definition of the record type. Example:  
`type record MYREC { integer a, integer b }`  
`mp_myRec := { b:=2, a:=1 }`
- The “\*” matching symbol can be used for mandatory fields (in TTCN-3 this cannot be used directly but indirectly any field of a variable template can be set to “\*”).

In module parameter section only constant values can be used which have no references to other values and do not call any predefined functions.

Example:

```
[MODULE_PARAMETERS]
par1 := -5
MyModule1.par2 := "This is a string\n"
MyModule1.par3 := {
  ethernet_header := {
    source_address := '000100010005'O,
    destination_address := '0008C7993605'O,
    ether_type := 34525
  },
  ipv6 := {
    header := {
      version := 6,
      traffic_class := 0,
      flow_label := 0,
      payload_length := 0,
      next_header := 58,
      hop_limit := 255,
      source_address := 'FE80000000000000020100FFFE010005'O,
      destination_address := 'FE800000000000000208C7FFFE993605'O
    },
    extension_headers := {
      {
        hop_by_hop_options_header := {
          next_header := 1,
          header_length := 2,
          options := '13'O
        }
      }
    }
  },
  data := {
    f_router_advertisement := {
      icmp_type := 134,
      code := 0,
      checksum := 0,
      hop_limit := 255,
      m_bit := '0'B,
      o_bit := '0'B,
      reserved := '000000'B,
      lifetime := 600,
      reachable_time := 300000,
      retrans_timer := 1000,
      options := {

par_record_of_int[6] := 7
MyModule1.par3.ethernet header.ether type := 34526

```

## 7.2 [LOGGING]

The executable test program produces a log file during its run. The log file contains important test execution events with time stamps<sup>24</sup>. This section explains how to set the log file name and the event classes to be logged. Logging may be directed to file or displayed on console (standard error).

Various options can be set in the section `[LOGGING]`. They affect the format and appearance of the test execution logs. Any option may be omitted; that is, each has a default value that is used if the option is omitted. If the same option is present several times in a configuration file only the latest value will take effect; the previously assigned values are ignored and a warning message is issued during configuration file processing.

### 7.2.1 LoggerPlugins

TITAN is equipped with an extensible logging architecture. The test execution events are directed towards the logger plugin interface. This interface can host arbitrary number of logger plugins.

The logging can be statically and dynamically loaded.

The default logging is the statically loaded built in logging.

The dynamically loaded logging can be the built in LegacyLogger, the plugins shipped with TITAN (see [7.2.2]) or user created dynamically linked plugins (for advanced users, see chapter 3 in [16]).

**When using dynamically loaded logger plugins it is very important to use the dynamic runtime library of TITAN, this can be done by using the `-l` switch when generating the makefile.**

<sup>24</sup> The maximal resolution of time stamps is 1  $\mu$ s, but it depends on your operating system. The highest accuracy can be achieved on UNIX systems, while it is only 1 ms on Windows NT and 10 ms on Windows 9x. In the latter cases trailing zeros will appear at the end of each time stamp.

Prepared (Subject resp) ETHBAAT Jeno Balasko		No. 2/198 17-CRL 113 200/5 Uen		
Approved (Document resp) ETHLEL Elemer Lelik	Checked ETHGRY	Date 2015-05-15	Rev C	Reference

The desired logger plugins need to be set in the `LoggerPlugins` option. The `LoggerPlugins` option takes a non-empty, comma separated list of logger plugin settings. These settings can be specified in the following ways:

- A logger plugin identifier followed by an assignment and a quoted string containing the plugin location. E.g. `LoggerPlugins := { plugin1 := "/absolute/path/to/plugin1.so" }` or `LoggerPlugins := { plugin1 := "/absolute/path/to/plugin1" }`. The identifier of a logger plugin is determined by its author can be learned from its documentation. The plugin location includes the file name of the plugin with an optional file system path prefix. A logger plugin is a dynamically linked shared object thus the logger plugin typically resides in a `.so` file. When the path prefix is missing or a relative path is used then TITAN attempts to locate the plugin in the path specified in the `LD_LIBRARY_PATH` environment variable. The plugin file name can be provided in two different ways: either by specifying the whole file name (ending with `.so`) or by specifying only the base of the name (omit the `.so` ending). The latter method is preferred because a logger plugin usually consists of 4 different shared library files and the proper file must be selected. The 4 different versions correspond to the single/parallel mode and the load/function test TITAN runtimes. If the file name ending is not provided the executable will determine it automatically, but if the whole file name is provided then it must correspond to the runtime which is actually used by the executable.
- A single logger plugin identifier. E.g. `LoggerPlugins := { plugin1 }`. In this case there should be a logger plugin named `plugin1.so` in one of the paths specified in the `LD_LIBRARY_PATH` environment variable.

Please note, that if TITAN is unable to locate any of the listed logger plugins, it will quit immediately with an error message. So, if the `LoggerPlugins` option is used, take special care to set `LD_LIBRARY_PATH` correctly or use absolute paths when specifying the plugins. There is a built-in logger plugin in TITAN, which provides the usual text-based logging format. This plugin is used when the `LoggerPlugins` option is omitted or it was listed explicitly in the list with the `LegacyLogger` case insensitive identifier. Since it's not possible to specify the path for this special, built-in logger plugin, only the second (with no path) specification mode is applicable here.

The logger plugins are responsible for the “final appearance” of the test execution log. The current TITAN distribution comes with a single logger plugin but it also supports user written logging plugins. The built-in `LegacyLogger` plugin produces log files and console log entries with similar content to elder TITAN revisions.

In case of overlapping plugin settings in multiple `LoggerPlugins` options, all configured plugins are attached to the list of existing plugins and take part in logging (i.e. do not overwrite them).

Prepared (Subject resp) ETHBAAT Jenö Balasko		No. 2/198 17-CRL 113 200/5 Uen		
Approved (Document resp) ETHLEL Elemer Lelik	Checked ETHGRY	Date 2015-05-15	Rev C	Reference

The configured logger plugins are valid for each test component unless otherwise configured (see coming subsection).

It is possible to reference all the listed plugins with `*` to e.g. assign the same parameters and values for multiple plugins. However, plugin configuration through `*` will not have an effect on plugin parameters, whose value was set previously by referencing explicitly the exact plugin using its name and optionally the component identifier it is configured for.

Logger plugins can be configured with arbitrary name-value pairs in the configuration file (see 7.2.16). E.g. `*.*.param1 := "value1"` will set the `param1` parameter to a string `value1` for all, not explicitly configured logger plugins on all test components. Logger plugins can ignore unknown parameters.

Each logger plugin has 4 `.so` files. The following table contains the names of the 4 different cases if the base file name (this is not the name of the plugin, library file names start with "lib") of the plugin is "libplugin":

*Note:*

The preferred method of specifying the above logger plugin in the configuration file is:

```
LoggerPlugins := { MyPluginName := "libplugin" }
```

The name `MyPluginName` is the name of the plugin and can be different than the library file names. If the full plugin file name is provided ( "libplugin.so, libplugin-parallel.so, etc.) then care must be taken to always use the name that corresponds to the mode in which the executable is running.

#### 7.2.1.1 Component-based Logger Plugin Settings

It is possible to associate an individual set of logger plugins for each test component. The component designation can be:

- the component name as given in the command `create`,
- the component reference (though using component references as identifiers is not recommended as this is a tool dependent identifier),
- the symbol `*` meaning all valid test components or
- the keyword `mtc` in the case of the Main Test Component.

The component name, if present, precedes the keyword `LoggerPlugins`. They are separated by a dot (`.`). The absent component reference is equivalent to `*.LoggerPlugins` meaning all valid test components.

Prepared (Subject resp) ETHBAAT Jenő Balasko		No. 2/198 17-CRL 113 200/5 Uen		
Approved (Document resp) ETHLEL Elemer Lelik	Checked ETHGRY	Date 2015-05-15	Rev C	Reference

## 7.2.2 Dynamically Loaded Logger Plugins Shipped with TITAN

Anyone can write a logger plugin to use with TITAN, but there are some widely used plugins that were made part of TITAN. These are available in the `$(TTCN3_DIR)/lib` sub-directory. Usually `LD_LIBRARY_PATH` contains this directory, if not then it should either be added to it or the path to the `.so` file has to be specified.

### 7.2.2.1 JUnitLogger Plugin

It outputs XML files in JUnit format. This format is needed by Hudson/Jenkins, a continuous integration test tool. The XML files written by this logger plugin are a subset of the JUnit XML output format.

At first select dynamic linking at Makefile generation according to 7.2.1.

To load the plugin the section [LOGGING] of the runtime configuration file should contain the following line:

```
LoggerPlugins := { JUnitLogger := "libjunitlogger" }
```

The plugin has 2 parameters:

`filename_stem` : set the output file name, the name will start with the string specified in this parameter and end with `"-<process_id>.log"`. The default value is `"junit-xml"`.

`testsuite_name` : the name of the test suite, this will be written into the XML file.

*Example 1:* Simplest HelloWorld example.

Source file (`hello.ttcn`):

```
module hello {
  type component CT {}
  testcase tc1() runs on CT {
    log("Hello Titan!");
    setverdict(pass,"Everything is ok");
  }

  testcase tc2() runs on CT {
    log("Hello Titan!");
    setverdict(fail,"Something was wrong");
  }
  control {
    execute(tc1());
    execute(tc2());
  }
}
```

Configuration file (`cfg.cfg`):

```
[LOGGING]
LogSourceInfo := Yes
SourceInfoFormat := Single
LoggerPlugins := { JUnitLogger := "libjunitlogger" }
*.JUnitLogger.filename_stem := "MyJUnitLogFile"
*.JUnitLogger.testsuite_name := "myJUnitTest"

[EXECUTE]
```

Prepared (Subject resp) ETHBAAT Jeno Balasko		No. 2/198 17-CRL 113 200/5 Uen		
Approved (Document resp) ETHLEL Elemer Lelik	Checked ETHGRY	Date 2015-05-15	Rev C	Reference

```
hello.control
```

The makefile was generated by the command `makefilegen -fl hello.ttcn`.

The executable was executed by the command `ttcn3_start hello cfg.cfg`.

After running the log file name was `MyJUnitLogFile-6426.log`, its content was :

```
<?xml version="1.0"?>
<testsuite name='myJUnitTest'><!-- logger name="JUnitLogger" version="v1.0" -->
<!-- Testcase tc1 started -->
<!-- Testcase tc1 finished in 0.000399, verdict: pass, reason: Everything is ok
-->
  <testcase classname='hello' name='tc1' time='0.000399'>
    </testcase>
<!-- Testcase tc2 started -->
<!-- Testcase tc2 finished in 0.000225, verdict: fail, reason: Something was
wrong -->
  <testcase classname='hello' name='tc2' time='0.000225'>
    <failure type='fail-verdict'>Something was wrong

        hello.ttcn:14 hello control part
        hello.ttcn:10 tc2 testcase
    </failure>
  </testcase>
</testsuite>
```

### ***Format of the results***

The results are included in testcases (between `<testcase>` tags) within a testsuite (between `<testsuite>` tags).

The testsuite has only one attribute “name” which contains the name of the testsuite.

Each testcase starts with two xml style comments which is followed by a `<testcase>` xml tag.

#### ***The comments***

Each testcase starts with the following two xml comments:

- `<!-- Testcase “name of the testcase” started -->`
- `<!-- Testcase “name of the testcase” finished in “execution time is seconds”, verdict:”verdict” -->`

This is followed by a `<testcase>` tag.

#### ***The <testcase> tag***

The `<testcase>` tag has the following attributes:

- `classname='name of the module'`
- `name='name of the testcase'`

Prepared (Subject resp) ETHBAAT Jeno Balasko		No. 2/198 17-CRL 113 200/5 Uen		
Approved (Document resp) ETHLEL Elemer Lelik	Checked ETHGRY	Date 2015-05-15	Rev C	Reference

- time='execution duration in seconds'

Depending of the verdict the <testcase> may have element contents which can be the following:

*Verdict: pass*

No children

*Verdict: fail*

Has the following element content with the following attribute:

<failure type='fail-verdict'>

The <failure> tag can have several of the following text contents – each in a separate line (see results log example above):

- control part
- testcase
- altstep
- function
- external function
- template

Each line contains “filename:linenumber identifier definition”, where each of the items mean the following:

- filename:linenumber – the file and the line where the test failed
- identifier – the identifier depending on the definition, e.g. the classname in case of “control part” or the name of the test in case of “testcase”
- definition – see the list in <failure> tag text content

This is a simple stacktrace of the failure.

*Verdict: none*

<skipped>no verdict</skipped>

*Verdict: inconclusive*

No children

*Verdict: error*

Prepared (Subject resp) ETHBAAT Jeno Balasko		No. 2/198 17-CRL 113 200/5 Uen		
Approved (Document resp) ETHLEL Elemer Lelik	Checked ETHGRY	Date 2015-05-15	Rev C	Reference

Has the following element content with the following attribute:

```
<error type='DTE'>
```

The `<error>` tag has the text contents containing the reason of the error.

### *XSD validation*

This is the xsd file to validate the xml generated by the plugin:

```
<?xml version="1.0" encoding="UTF-8" ?>
<xs:schema xmlns:xs="http://www.w3.org/2001/XMLSchema">

  <xs:element name="failure">
    <xs:complexType mixed="true">
      <xs:attribute name="type" type="xs:string" use="optional"/>
    </xs:complexType>
  </xs:element>

  <xs:element name="skipped" type="xs:string"/>

  <xs:element name="error">
    <xs:complexType mixed="true">
      <xs:attribute name="type" type="xs:string" use="optional"/>
    </xs:complexType>
  </xs:element>

  <xs:element name="testcase">
    <xs:complexType>
      <xs:sequence>
        <xs:element ref="skipped" minOccurs="0" maxOccurs="1"/>
        <xs:element ref="error" minOccurs="0" maxOccurs="unbounded"/>
        <xs:element ref="failure" minOccurs="0" maxOccurs="unbounded"/>
      </xs:sequence>
      <xs:attribute name="classname" type="xs:string" use="required"/>
      <xs:attribute name="name" type="xs:string" use="required"/>
      <xs:attribute name="time" type="xs:string" use="required"/>
    </xs:complexType>
  </xs:element>

  <xs:element name="testsuite">
    <xs:complexType>
      <xs:sequence>
        <xs:element ref="testcase" minOccurs="0"
maxOccurs="unbounded"/>
      </xs:sequence>
      <xs:attribute name="name" type="xs:string" use="required"/>
    </xs:complexType>
  </xs:element>

</xs:schema>
```

#### 7.2.2.2 JUnitLogger2 Plugin

It outputs XML files in JUnit format. This format is needed by Hudson/Jenkins, a continuous integration test tool. The XML files written by this logger plugin are a subset of the JUnit XML output format.

The JUnitLogger2 plugin works as the JUnitLogger plugin (explained in **Error! Reference source not found.**) with the following exceptions:

- Configuration file (`cfg.cfg`):

Prepared (Subject resp) ETHBAAT Jeno Balasko		No. 2/198 17-CRL 113 200/5 Uen		
Approved (Document resp) ETHLEL Elemer Lelik	Checked ETHGRY	Date 2015-05-15	Rev C	Reference

In the configuration file when specifying the logger plugin libjunitlogger2 should be written.

```
[LOGGING]
LogSourceInfo := Yes
SourceInfoFormat := Single
LoggerPlugins := { JUnitLogger := "libjunitlogger2" }
*.JUnitLogger.filename_stem := "MyJUnitLogFile"
*.JUnitLogger.testsuite_name := "myJUnitTest"
```

- The results are included in testcases (between <testcase> tags) within a testsuite (between <testsuite> tags) like the JUnitLogger but the testsuite has attributes other than “name” which contains the name of the testsuite.

New attributes:

tests – number of all testcases executed

failures – number of testcases whose final verdict is fail

errors – number of testcases that encountered an error

skipped – number of testcases with a none verdict

time – the time in seconds from the start of the tests until all the testcases executed.

- XML comments are not added to the output.
- XSD:

Prepared (Subject resp) ETHBAAT Jenö Balasko		No. 2/198 17-CRL 113 200/5 Uen		
Approved (Document resp) ETHLEL Elemer Lelik	Checked ETHGRY	Date 2015-05-15	Rev C	Reference

```
<?xml version="1.0" encoding="UTF-8" ?>
<xs:schema xmlns:xs="http://www.w3.org/2001/XMLSchema">

  <xs:element name="failure">
    <xs:complexType mixed="true">
      <xs:attribute name="type" type="xs:string" use="optional"/>
    </xs:complexType>
  </xs:element>

  <xs:element name="skipped" type="xs:string"/>

  <xs:element name="error">
    <xs:complexType mixed="true">
      <xs:attribute name="type" type="xs:string" use="optional"/>
    </xs:complexType>
  </xs:element>

  <xs:element name="testcase">
    <xs:complexType>
      <xs:sequence>
        <xs:element ref="skipped" minOccurs="0"
maxOccurs="1"/>
        <xs:element ref="error" minOccurs="0"
maxOccurs="unbounded"/>
        <xs:element ref="failure" minOccurs="0"
maxOccurs="unbounded"/>
      </xs:sequence>
      <xs:attribute name="classname" type="xs:string"
use="required"/>
      <xs:attribute name="name" type="xs:string" use="required"/>
      <xs:attribute name="time" type="xs:string" use="required"/>
    </xs:complexType>
  </xs:element>

  <xs:element name="testsuite">
    <xs:complexType>
      <xs:sequence>
        <xs:element ref="testcase" minOccurs="0"
maxOccurs="unbounded"/>
      </xs:sequence>
      <xs:attribute name="name" type="xs:string" use="required"/>
      <xs:attribute name="tests" type="xs:int" use="required"/>
      <xs:attribute name="failures" type="xs:int" use="required"/>
      <xs:attribute name="errors" type="xs:int" use="required"/>
      <xs:attribute name="skipped" type="xs:int" use="required"/>
      <xs:attribute name="time" type="xs:string" use="required"/>
    </xs:complexType>
  </xs:element>

</xs:schema>
```

### 7.2.2.3 TSTLogger plugin

The TestStatistics TITAN Logger plugin sends HTTP messages to the TestStatistics web based tool. TestStatistics has a web interface (<http://eta-teststatistics.rnd.ki.sw.ericsson.se/ts/login>) where the test result data can be examined. Currently the following messages are sent to the TestStatistics tool:

- Test suite started (tsstart)
- Test case started (tcstart)
- Test case finished (tcstop)

Prepared (Subject resp) ETHBAAT Jeno Balasko		No. 2/198 17-CRL 113 200/5 Uen		
Approved (Document resp) ETHLEL Elemer Lelik	Checked ETHGRY	Date 2015-05-15	Rev C	Reference

- Test suite finished (tsstop)
- Test case fail reason (tcfailreason)

The content of these messages is filled based on the log data and data given in the configuration file. Some data needs to be set as logger plugin parameters in the configuration file because it is needed by the TestStatistics tool but the TITAN log messages do not contain such information. The plugin parameters:

Name	Default value	Description
tst_host_name	"eta-teststatistics. rnd.ki.sw.ericsson.se"	TestStatistics web service host name
tst_service_name	"http"	TestStatistics web service name or port number
tst_tcstart_url	"/ts-rip/rip/tcstart"	Path for the tcstart message
tst_tcstop_url	"/ts-rip/rip/tcstop"	Path for the tcstop message
tst_tsstart_url	"/ts-rip/rip/tsstart"	Path for the tsstart message
tst_tsstop_url	"/ts-rip/rip/tsstop"	Path for the tsstop message
tst_tcfailreason_url	"/ts-rip/rip/tcfailreason"	Path for the tcfailreason message
dbUrl	"esekilx0007- sql5.rnd.ki.sw.ericsson.se:3314"	database URL
dbUser	"demo"	database user
dbPass	"demo"	plain text password of the user
dbName	"teststatistics_demo"	name of the database
log_plugin_debug	"0"	The logger plugin will print some debug information to the console if this value is not "0".
testConfigName	"DefaultConfigName"	name of this specific configuration of the test suite
suiteName	"DefaultSuiteName"	name of test suite
executingHost	the host name of the MTC (determined with gethostname())	host where the test was executed

Prepared (Subject resp) ETHBAAT Jenö Balasko		No. 2/198 17-CRL 113 200/5 Uen		
Approved (Document resp) ETHLEL Elemer Lelik	Checked ETHGRY	Date 2015-05-15	Rev C	Reference

sutId	"0.0.0.0"	IP address of SUT
sutName	"DefaultSUTName"	name of SUT
IsvMajor	"1"	major version number of SUT
IsvMinor	"0"	minor version number of SUT
runByUser	Login name of the user running the MTC (determined with getlogin())	name of user running the tests
projectName	"DefaultProjectname"	name of the project
productName	"DefaultProductName"	name of the product
productVersion	"0.0"	version of the product
configType	"configType"	
configVersion	"configVersion"	
testType	"testType"	
logLink	"default_log_location"	absolute location of log files
logEnd	"default_web_log_dir"	log directory relative to web server root
reportEmail	automatically set to < runByUser > +"@ericsson.com"	who is to be notified via email
reportTelnum	"0"	where to send the SMS notification

The parameters starting with "tst\_" should be modified only if the TestStatistics tool is moved to another location on the intranet.

There are 4 parameters for setting the database connection, the database can also be selected on the web interface, all information sent by TITAN will be stored there. The default values will use a demo database which can be used for experimentation.

All parameters have default values, thus the plugin can be used even without setting any parameters. However some parameters should be set to a meaningful value, such as the suiteName or the projectName. An example from a configuration file:

```
LoggerPlugins := { TSTLogger := "libtstlogger" }
```

Prepared (Subject resp) ETHBAAT Jeno Balasko		No. 2/198 17-CRL 113 200/5 Uen		
Approved (Document resp) ETHLEL Elemer Lelik	Checked ETHGRY	Date 2015-05-15	Rev C	Reference

```
*.TSTLogger.testConfigName = "Hiper Giga Test"  
*.TSTLogger.sutId = "11.22.33.44"  
*.TSTLogger.projectName = "MagicProject"  
*.TSTLogger.suiteName = "Super Test Suite"  
*.TSTLogger.lsvMajor = "3"  
*.TSTLogger.lsvMinor = "14"
```

To load the plugin the runtime configuration file should contain the following line:

```
LoggerPlugins := { TSTLogger := "libtstlogger" }
```

### 7.2.3 LogFile

Option `LogFile` stands for the name of the log file. A string value is expected, which is interpreted as a skeleton to determine the file name. To make the file name handling more flexible the string may contain special metacharacters, which are substituted dynamically during test execution.

[Table 12](#) contains the list of available metacharacters in alphabetical order. Any unsupported metacharacter sequence, that is, if the `%` character is followed by any character that is not listed in the table below or a single percent character stays at the end of the string, will remain unchanged.

Prepared (Subject resp) ETHBAAT Jeno Balasko		No. 2/198 17-CRL 113 200/5 Uen		
Approved (Document resp) ETHLEL Elemer Lelik	Checked ETHGRY	Date 2015-05-15	Rev C	Reference

Table 12 Available metacharacters for setting log file names

Meta-character	Substituted with . . .
%c	the name of the TTCN-3 test case that the PTC belongs to.
%e	the name of the TTCN-3 executable. The <code>.exe</code> suffix (on Windows platforms) and the directory part of the path name (if present) are truncated.
%h	the name of the computer returned by the <code>gethostname(2)</code> system call. This usually does not include the domain name.
%i	the sequence number of the log fragment.
%l	the login name of the current user. If the login name cannot be determined (e.g. the current UNIX user ID has no associated login name) an empty string is returned.
%n	<ul style="list-style-type: none"><li>the name of the test component if the PTC has been given a name with the command <code>create</code> in the TTCN-3 <code>create</code> operation; an empty string otherwise.</li><li>the string <code>HC</code> if the logfile is generated by a Host Controller</li><li>the string <code>MTC</code> if the component is the Main Test Component (both in parallel and in single mode)</li></ul>
%p	the process ID ( <code>pid</code> ) of the UNIX process that implements the current test component. The <code>pid</code> is written in decimal notation.
%r	the component reference or component identifier. On PTCs it is the component reference (an integer number greater or equal to 3) in decimal notation. On the Main Test Component, Host Controller or in single mode the strings <code>mtc</code> , <code>hc</code> or <code>single</code> are substituted, respectively.
%s	the default suffix for the log files without the leading dot. Now it always results in string <code>log</code> , but future versions may support log file compression. In this case the suffix will depend on the chosen compression method.
%t	the TTCN-3 component type. Note: The MTC and HC have no dedicated component type since they can implement several component types in different test cases.
%%	a single <code>%</code> character.

The outcome of substitution will result in the name of the log file. It may resolve either to a simple file name or to an absolute or relative path. The relative pathnames are always related to the current working directory of the executable tests in single mode or that of the Host Controller in parallel mode, respectively. If the pathname contains one or more nonexistent directories, those directories (and/or subdirectories) will be automatically created with permissions `0755` before the log file is opened.

Prepared (Subject resp) ETHBAAT Jenő Balasko		No. 2/198 17-CRL 113 200/5 Uen		
Approved (Document resp) ETHLEL Elemer Lelik	Checked ETHGRY	Date 2015-05-15	Rev C	Reference

If the given string or the result of substitution is empty, no log file will be created and only console logging will be performed regardless the setting of `FileMask`. Empty log files will not be created when logging to files is completely disabled (i.e. `FileMask` is set to `LOG_NOTHING`) even if the value of `LogFile` would yield a valid file name.

In parallel mode the user must ensure that the resulting log file names are unique for every component. Otherwise, if several components try to write into the same log file, the contents of the log will be unpredictable. The uniqueness is automatically provided if the host name (`%h`) and the component reference (`%r`) or the process ID (`%p`) is included in the file name.

If testcase name (`%c`) or component name (`%t`) is included, the log file name may change during runtime. A new log file will be created/opened in this case. If a log file with the new name already exists, it is overwritten by default. Because of this, it is **highly recommended** to set `AppendFile` (see 0 below) to `Yes` if `LogFile` contains `%c` or `%t`.

If omitted, the default value for option `LogFile` is `%e-part%i.%s` in single mode and `%e.%h-%r-part%i.%s` in parallel mode, respectively. This ensures backward compatibility with earlier versions in parallel mode and follows the most commonly used file naming convention in single mode.

## 7.2.4 FileMask

Option `FileMask` determines which events will be written to the log file and which ones will be filtered out.

### 7.2.4.1 Category-based Filtering

Table 13 enumerates the first level groups of events (that is, logging categories) along with a symbolic constant. The selected constants separated by a pipe (`|`) will determine what will be logged. When `FileMask` is omitted from the configuration file, its default value (`LOG_ALL`) is applied.

Some of the first level logging categories may be divided in second level subcategories to get a finer logging granularity. These categories are listed in the tables 11 to 21. First level categories and second level subcategories may be mixed in the option.

Prepared (Subject resp) ETHBAAT Jeno Balasko		No. 2/198 17-CRL 113 200/5 Uen		
Approved (Document resp) ETHLEL Elemer Lelik	Checked ETHGRY	Date 2015-05-15	Rev C	Reference

First level logging categories may be considered as notational convenience. They are maintained also for backward compatibility: legacy configuration files containing only first level categories will continue to work unmodified. However, the resulting log file may look different, as event categories have been modified; some messages, mostly `PARALLEL` and `FUNCTION`, have changed category, usually to `EXECUTOR`. When a first level logging category is included in the option `FileMask`, all second level subcategories pertaining to it will also be implicitly included, thus, it is redundant to list one or more subcategories along with the concerned first level category.

#### 7.2.4.2 Component and Plugin Based Filtering

It is possible to filter events based on the identity of the component generating them. For component designation it is recommended to use the component name given in the command `create` or the keyword `mtc`; latter one in the case of the Main Test Component. Using component numbers as identifiers is not recommended as this is a tool dependent identifier.

The component name, if present, precedes the keyword `FileMask`. They are separated by a dot (`.`).

It is also possible to apply the filtering on selected logger plugins of a component. The identifier of the desired logger plugin is appended after the component designation. The component and plugin identifiers are separated by a dot (`.`).

### 7.2.5 ConsoleMask

Option `ConsoleMask` determines which events will be written to the console and which ones will be filtered.

#### 7.2.5.1 Category-based Filtering

Table 13 enumerates the first level groups of events (that is, logging categories) along with a symbolic constant. The selected constants separated by a pipe (`|`) will determine what will be logged. When `ConsoleMask` is omitted from the configuration file, its default value (`ERROR|WARNING|ACTION|TESTCASE|STATISTICS`) is applied.

Some of the first level logging categories may be divided in second level subcategories to get a finer logging granularity. These categories are listed in the tables 11 to 21. First level categories and second level subcategories may be mixed in the option.

Prepared (Subject resp) ETHBAAT Jeno Balasko		No. 2/198 17-CRL 113 200/5 Uen		
Approved (Document resp) ETHLEL Elemer Lelik	Checked ETHGRY	Date 2015-05-15	Rev C	Reference

First level logging categories may be considered as notational convenience. They are maintained also for backward compatibility: legacy configuration files containing only first level categories will continue to work unmodified. However, the resulting log file may look different, as event categories have been modified; some messages, mostly `PARALLEL` and `FUNCTION`, have changed category, usually to `EXECUTOR`. When a first level logging category is included in the option `ConsoleMask`, all second level subcategories pertaining to it will also be implicitly included, thus, it is redundant to list one or more subcategories along with the concerned first level category.

In single mode the console log messages are written to the standard error of the ETS. For the interpretation of console logging in parallel mode see section 12.3.3. of the TITAN User Guide ([13]).

**WARNING:** Please note that neither the timestamp nor the event type, nor location information is printed on the console.

#### 7.2.5.2 Component and Plugin Based Filtering

It is possible to filter events based on the identity of the component generating them. For component designation it is recommended to use the component name given in the command `create` or the keyword `mtc`; latter one in the case of the Main Test Component. Using component numbers as identifiers is not recommended as this is a tool dependent identifier.

The component name, if present, precedes the keyword `ConsoleMask`. They are separated by a dot (.).

Table 13 First level (coarse) log filtering

Logging categories	Symbolic constant <sup>25</sup>
TTCN–3 action(...) statements (No subcategory is implemented)	ACTION
Debug messages in Test Ports and external functions (For subcategories see <a href="#">Table 14</a> )	DEBUG
Default operations (activate, deactivate, return) (For subcategories see <a href="#">Table 15</a> )	DEFAULTOP
Dynamic test case errors (e.g. snapshot matching failures) (No subcategory is implemented)	ERROR
Internal TITAN events (For subcategories see <a href="#">Table 16</a> )	EXECUTOR
Random number function calls (For subcategories see Note: EXECUTOR_EXTCOMMAND is always logged, regardless of the user's settings. Table 17)	FUNCTION
Bitwise OR of all the above except MATCHING and DEBUG	LOG_ALL
Nothing to be logged	LOG_NOthing
Analysis of template matching failures in receiving port operations (For subcategories see <a href="#">Table 18</a> )	MATCHING
Parallel test execution and test configuration related operations (create, done, connect, map, etc.) (For subcategories see <a href="#">Table 19</a> )	PARALLEL
Port events (send, receive) (For subcategories see <a href="#">Table 21</a> )	PORTEVENT
Statistics of verdicts at the end of execution (For subcategories see <a href="#">Table 22</a> )	STATISTICS
The start, the end and the final verdict of test cases (For subcategories see <a href="#">Table 20</a> )	TESTCASE
Timer operations (start, stop, timeout, read) (For subcategories see <a href="#">Table 23</a> )	TIMEROP
User log(...) statements (No subcategory is implemented)	USER

<sup>25</sup> In order to be compatible with older configuration files, the following symbolic constants are also recognized: TTCN\_ERROR, TTCN\_WARNING, TTCN\_PORTEVENT, TTCN\_TIMEROP, TTCN\_VERDICTOP, TTCN\_DEFAULTOP, TTCN\_TESTCASE, TTCN\_ACTION, TTCN\_USER, TTCN\_FUNCTION, TTCN\_STATISTICS, TTCN\_PARALLEL, TTCN\_EXECUTOR, TTCN\_MATCHING and TTCN\_DEBUG. These constants have the same meaning as their counterparts without the prefix TTCN\_.

Final verdict of a test component (MTC or PTC)	VERDICTOP_FINAL
Other, non categorized log messages of the category	VERDICTOP_UNQUALIFIED

## 7.2.6 AppendFile

Option `AppendFile` controls whether the run-time environment shall keep the contents of existing log files when starting execution. The possible values are `Yes` or `No`. The default is `No`, which means that all events from the previous test execution will be overwritten.

This option can be used in both single and parallel modes. Its usefulness in single mode is obvious. If the executable test suite is started several times, the logs of the successive test sessions will be stored in the same single file after each other.

In parallel mode the naming of log files is automatic and is based on the host name and component references. The option is applicable to all log files: all of them will be either appended or overwritten. If the test execution is repeated several times with different configuration or test case selection, the same file may contain the log of totally different test components. When appending is enabled the log files can be interpreted after using the `logmerge` utility (see Section 13.1. of the TITAN User Guide, [\[13\]](#)). The option `AppendFile` guarantees only that no logged events will be lost during the entire test campaign.

Prepared (Subject resp) ETHBAAT Jeno Balasko		No. 2/198 17-CRL 113 200/5 Uen		
Approved (Document resp) ETHLEL Elemer Lelik	Checked ETHGRY	Date 2015-05-15	Rev C	Reference

### 7.2.7 TimeStampFormat

Option `TimeStampFormat` configures the formatting of timestamps in the log file. It can have three possible values: `Time` stands for the format `hh:mm:ss.microsec`. `DateTime` results in `yyyy/Mon/dd hh:mm:ss.microsec`. This is useful for long test durations (for instance, when a stability test runs for a couple of days). Using the third alternative (`Seconds`) results relative timestamps in format `s.microsec`. The time is related to the starting of the test component or test execution (i.e. this is the zero time). The default value for `TimeStampFormat` is `Time`.

### 7.2.8 ConsoleTimeStampFormat

Option `ConsoleTimeStampFormat` configures the formatting of timestamps in console log. It can have the same three values as `TimeStampFormat` can have: `Time`, `DateTime` and `Seconds` see [7.2.7]. If it is omitted (default) timestamp will not be inserted in the console log.

### 7.2.9 LogEventTypes

Option `LogEventTypes` indicates whether to include the symbolic event type (without the TTCN prefix) in each logged event immediately after the timestamp. This option can be useful for log post-filtering scripts. The possible values for `LogEventTypes` are `Yes`, `No`, `Detailed` and `Subcategories`.

The default is `No`: no events will be logged.

The setting `Yes` results a logfile containing event categories listed in

[Table 13](#).

The setting `Subcategories` (and the equivalent `Detailed`) produces a logfile containing both event categories and subcategories. Subcategories are listed in the tables 11 to 21.

In both single and parallel modes some log events are created before processing the configuration data. At this time the logging options (name of the log file, filter settings, timestamp format, etc.) are not known by the run-time environment, thus, these events are collected in a temporary memory buffer and are flushed to the log file when the processing of configuration file is finished. This implies that if the Host Controller is stopped in parallel mode before configuring it, no log file will be created at all.

Prepared (Subject resp) ETHBAAT Jenő Balasko		No. 2/198 17-CRL 113 200/5 Uen		
Approved (Document resp) ETHLEL Elemer Lelik	Checked ETHGRY	Date 2015-05-15	Rev C	Reference

### 7.2.10 SourceInfoFormat

Option `SourceInfoFormat` controls the appearance of the location information for the test events. The location information refers to a position in the TTCN-3 source code. It consists of the name of the TTCN-3 file and the line number separated by a colon character (:). Optionally, it may contain the name of the TTCN-3 entity (function, testcase, etc.) in parentheses that the source line belongs to. See also the option `LogEntityName` below.

The option can take one of the three possible values: `None`, `Single` and `Stack`. In case of `Single`, the location information of the TTCN-3 statement is logged that is currently being executed. When `Stack` is used the entire TTCN-3 call stack is logged. The logged information starts from the outermost control part or testcase and ends with the innermost TTCN-3 statement. An arrow (that is, the character sequence `->`) is used as separator between the stack frames. The value `None` disables the printing of location information.

The default value for `SourceInfoFormat` is `None`.

The location information is placed in each line of the log file between the event type or timestamp and the textual description of the event.

This option works only if the command line option `-L` is passed to the compiler (see section 6.1). This feature is useful for debugging new TTCN-3 code or for understanding the traces of complex control constructs. If the location information is not generated into the C++ code the executable tests run faster, which can be more important when doing performance tests.

Please note that the reception of messages or procedure calls can only occur while the run-time environment is taking a new snapshot. A new snapshot is taken when the testcomponent is evaluating a stand-alone receiving operation, an `alt` construct or a standalone `altstep` invocation. Thus, the location information of the incoming messages or calls points to the first line of the above statements. The log event belonging to a TTCN-3 operation can be the extraction of a message from the port queue and not the reception of an incoming message.

If the event has no associated line in the TTCN-3 source code (e.g. because it belongs to test environment startup or termination) and `SourceInfoFormat` is set to either `Single` or `Stack`, a single dash character (-) is printed into the log instead of the location information. This makes the automated processing of log files easier.

The obsolete option `LogSourceInfo` is also accepted for backward compatibility with earlier versions. Setting `LogSourceInfo := Yes` is equivalent to `SourceInfoFormat := Single`, and similarly `LogSourceInfo := No` means `SourceInfoFormat := None`.

Prepared (Subject resp) ETHBAAT Jeno Balasko		No. 2/198 17-CRL 113 200/5 Uen		
Approved (Document resp) ETHLEL Elemer Lelik	Checked ETHGRY	Date 2015-05-15	Rev C	Reference

### 7.2.11 LogEntityName

Option `LogEntityName` controls whether the name of the corresponding TTCN-3 entity (`function`, `testcase`, `altstep`, `control part`, etc.) shall be included in the location information. If this option is set to `Yes`, the file name and line number is followed by the name of the TTCN-3 entity within parentheses. The default value is `No`. The option has no effect if `SourceInfoFormat` is set to `None`.

### 7.2.12 LogFileSize

Option `LogFileSize` sets the upper limit for the log file size. The limitation prevents load tests or long duration tests from triggering dynamic test case error when the growing log file exceeds file system size limits or available disk space.

When the size limit is reached, the file is closed and a new log file will be created with an increased part number. For example, the first two log files when running `ExampleTestCase` in single mode will be `ExampleTestCase-part1.log` and `ExampleTestCase-part2.log`, respectively provided that the file name skeleton default values have not been modified (see section 0).

This option must be set together with `LogFileNumber`; see section 7.2.13.

The parameter value, a non-negative integer, is understood in kilobytes. The default value is 0, meaning that the file size is unlimited; or, to be precise, is only limited by the file system.

#### 7.2.12.1 Component and Plugin Dependent File Size

It is possible to set different file sizes based on the identity of the component generating the log. For component designation it is recommended to use the component name given in the parameter of the command `create` (or the keyword `mtc` for the Main Test Component). Using component numbers as identifiers is not recommended as this is a tool dependent identifier.

The component name, if present, precedes the keyword `LogFileSize`. The name and the keyword are separated by a dot (`.`).

It is also possible to limit the file size on selected logger plugins of a component. The identifier of the desired logger plugin is appended after the component designation. The component and plugin identifiers are separated by a dot (`.`).

Prepared (Subject resp) ETHBAAT Jeno Balasko		No. 2/198 17-CRL 113 200/5 Uen

### 7.2.13 LogFileName

Option `LogFileName`, a positive integer, sets the the maximum number of log files (fragments)<sup>28</sup> kept. If the log file number limit is reached, the oldest log file of the component will be deleted and logging continues in the next log fragment file.

The default value is 1, meaning that the number of log files equals one.

#### 7.2.13.1 Component and Plugin Dependent Fragment Number

It is possible to set different fragment limits based on the identity of the component generating the log. For component designation it is recommended to use the component name given in the parameter of the command `create` (or the keyword `mtc` for the Main Test Component). Using component numbers as identifiers is not recommended as this is a tool dependent identifier.

The component name, if present, precedes the keyword `LogFileName`. The name and the keyword are separated by a dot (.).

It is also possible to limit the number of log fragments on selected logger plugins of a component. The identifier of the desired logger plugin is appended after the component designation. The component and plugin identifiers are separated by a dot (.).

### 7.2.14 DiskFullAction

Option `DiskFullAction` determines TITAN behavior when writing to the log file fails.

If this option set to `Stop` test case execution continues without logging when an error occurs.

The setting `Retry` causes test case execution to continue without logging and TITAN attempts to restart logging activity periodically (events in the unlogged periods are lost). The retry period is set by default to 30 seconds and can be changed by a parameter. Example: `Retry(60)` doubles the period.

If the parameter is set to `Delete`, TITAN deletes the oldest log file and continues logging to a new log file fragment. If log writing fails again, the procedure is repeated until one two log files (the actual one and the previous one) are left. Further log writing failure causes a dynamic test case error.

---

<sup>28</sup> A new fragment emerges whenever the size of the log file reaches the limit set by `LogFileSize`.

Prepared (Subject resp) ETHBAAT Jeno Balasko		No. 2/198 17-CRL 113 200/5 Uen		
Approved (Document resp) ETHLEL Elemer Lelik	Checked ETHGRY	Date 2015-05-15	Rev C	Reference

The default behavior is `Error`. With this setting, writing error causes a runtime (dynamic) test case error.

#### 7.2.14.1 Component and Plugin Dependent Behavior

It is possible to set different error behavior based on the identity of the component generating the log. For component designation it is recommended to use the component name given in the parameter of the command `create` (or the keyword `mtc` for the Main Test Component). Using component numbers as identifiers is not recommended as this is a tool dependent identifier.

The component name, if present, precedes the keyword `DiskFullAction`. The name and the keyword are separated by a dot (`.`).

It is also possible configure different error behavior on selected logger plugins of a component. The identifier of the desired logger plugin is appended after the component designation. The component and plugin identifiers are separated by a dot (`.`).

#### 7.2.15 MatchingHints

Option `MatchingHints` controls the amount and format of log messages describing template matching failures. These are written during port receive operations as logging category `MATCHING`, and as a response to TTCN-3 `log(match (...))` statements as logging category `USER`.

There are two possible values: `Compact` and `Detailed`.

When the `Detailed` option is in effect, a field-by-field description of the value and template is logged, followed by additional hints when matching set-of types. Example:

Prepared (Subject resp) ETHBAAT Jeno Balasko		No. 2/198 17-CRL 113 200/5 Uen		
Approved (Document resp) ETHLEL Elemer Lelik	Checked ETHGRY	Date 2015-05-15	Rev C	Reference

```

{
  {
    field_rr1 := 1,
    field_rr2 := 2
  },
  {
    field_rr1 := 3,
    field_rr2 := 4
  }
} with {
  {
    field_rr1 := 1,
    field_rr2 := 2
  },
  {
    field_rr1 := 3,
    field_rr2 := 5
  }
} unmatched Some hints to find the reason of mismatch: {
  value elements that have no pairs in the template: {
    field_rr1 := 3,
    field_rr2 := 4
  } at index 1,
  template elements that have no pairs in the value: {
    field_rr1 := 3,
    field_rr2 := 5
  } at index 1,
  matching value <-> template index pairs: {
    0 <-> 0
  },
  matching unmatched value <-> template index pairs: {
    1 <-> 1: {
      {
        field_rr1 := 3 with 3 matched,
        field_rr2 := 4 with 5 unmatched
      }
    }
  }
}

```

The printout is similar to the TTCN-3 assignment notation for the entire structure.

When the `Compact` option is in effect, fields and structures that match are omitted in order to pinpoint the reason why the entire match operation failed. Every mismatch is represented as a path from the outermost (containing) type to the innermost simple type that failed to match. This is similar to a mixture of dot notation referencing fields of record/set types and indexed notation referencing elements of record-of/set-of types, as it would be used to reference the innermost member of a structured type:

- Mismatched fields of a record/set are represented by the field name preceded by a dot (a.k.a. full stop).
- Mismatched elements of a record-of are represented by the index in square brackets.
- Mismatched elements of a set-of are represented by the indexes of the mismatching elements in the value and the template, separated by a two-headed arrow.

Prepared (Subject resp) ETHBAAT Jeno Balasko		No. 2/198 17-CRL 113 200/5 Uen		
Approved (Document resp) ETHLEL Elemer Lelik	Checked ETHGRY	Date 2015-05-15	Rev C	Reference

Example: The following line is the equivalent of the nested display above when the `Compact` option is in effect instead of `Detailed`.

```
[1 <-> 1].field_rr2 := 4 with 5 unmatched
```

This means that the second element (indexing is 0-based) of the value didn't match the second element of the template because `field_rr2` in the value was 4 whereas `field_rr2` in the template was 5.

The default value of `MatchingHints` is `Compact`.

## 7.2.16 EmergencyLogging

Titan implements an emergency logging feature. The purpose of this feature is to help diagnose errors by logging events that would normally be suppressed, for example if only a few event types are logged (e.g. to minimize I/O overhead or log file size) and all the other log events are discarded. If something unexpected occurs (e.g. Dynamic Testcase Error), it can be difficult to diagnose the problem, but there is no way to recover the discarded events.

With emergency logging, log events which are not written to the log file can be stored in a ring buffer. In case of an error, the stored events can be recovered from the buffer and written to the log. Because the buffered events are closest in time to the error, they are most likely to be helpful in diagnosing the cause.

The value of the `EmergencyLogging` option is the ring buffer size (the number of log events that are kept). The default value is zero, which turns off the emergency logging feature.

## 7.2.17 EmergencyLoggingBehaviour

Buffering of events can be performed in two ways:

- Buffering only selected messages. This option is selected with the `BufferMasked` value of the `EmergencyLoggingBehaviour` option. This is the default behaviour. Log events included by `EmergencyLoggingMask` are buffered, others are sent to the plugins to be logged or discarded. This method can not guarantee that timestamps of the log events passed to the plugins are always monotonically increasing. Monotonically increasing timestamps are a requirement for `ttn3_logmerge`. The `LegacyLogger` plugin ensures that the requirements of `ttn3_logmerge` are satisfied by writing the emergency log messages to a separate log file.

Prepared (Subject resp) ETHBAAT Jenö Balasko		No. 2/198 17-CRL 113 200/5 Uen		
Approved (Document resp) ETHLEL Elemer Lelik	Checked ETHGRY	Date 2015-05-15	Rev C	Reference

- Buffer all messages. This option is selected with the `BufferAll` value of the `EmergencyLoggingBehaviour` option. All events are initially placed in the buffer. If the buffer is full, the oldest buffered event is extracted and sent to the plugins to be logged. If an error occurs, all stored events are extracted and logged. This method guarantees that all log events passed to the plugins have their timestamps in a monotonically increasing order. In this case there is no separate emergency log file.

## 7.2.18 EmergencyLoggingMask

Option `EmergencyLoggingMask` determines which events will be saved in the emergency logging buffer when the value of `EmergencyLoggingBehaviour` is `BufferMasked`.

## 7.2.19 BNF productions for this section

```

AppendFile := No
TimeStampFormat := DateTime
ConsoleTimeStampFormat := Time
LogEventTypes := No
SourceInfoFormat := Single
LogEntityName := Yes
MatchingHints := Detailed
EmergencyLogging := 2000
EmergencyLoggingBehaviour := BufferAll
EmergencyLoggingMask := LOG_ALL
```

## 7.3 [TESTPORT\_PARAMETERS]

In this section you can specify parameters that are passed to Test Ports. Each parameter definition consists of a component name, a port name, a parameter name and a parameter value. The component name can be either an identifier that is assigned to the component in the `create` operation (see section 4.2) or an integer value, which is interpreted as component reference<sup>29</sup>. The port and parameter names are identifiers while the parameter value must be always a `charstring` (with quotation marks). Instead of component name or port name (or both of them) the asterisk (\*) sign can be used, which means "all components" or "all ports of the component".

If the keyword `system` is used as a component identifier, the parameter is passed to all ports of all components that are mapped to the given port of the test system interface. In this case the port identifier refers to the port of the test system and not the port of a TTCN-3 test component. These parameters are passed to the appropriate Test Port during the execution of `map` operations because the future mappings are not known at test component initialization. The asterisk ("\*") sign can also be used as port name with the component identifier `system`. This wildcard means, of course, all ports of the Test System Interface (that is, the parameter will be passed during all `map` operations).

The names and meaning of Test Port parameters depend on the Test Port that you are using; for this information please consult the user documentation of your Test Port. It is the Test Port writer's responsibility to process the parameter names and values. For the details of Test Port API see the section "Parameter setting function" in [16].

<sup>29</sup> Using numeric component references is not recommended because they depend on the sequence of previously executed test cases and can be different in subsequent test runs.

### 7.3.1 BNF Productions for this Section

```
TestPortParametersSection ::= "[TESTPORT_PARAMETERS]" {TestPortParameter}
TestPortParameter ::= ComponentId "." PortName "." PortParameterName
AssignmentChar PortParameterValue [SemiColon]
ComponentId ::= Identifier | Number | MTCKeyword | SystemKeyword | "*"
MTCKeyword ::= "mtc"
SystemKeyword ::= "system"
PortName ::= Identifier {ArrayRef} | "*"
ArrayRef ::= "[" IntegerValue "]"
PortParameterName ::= Identifier
PortParameterValue ::= StringValue
```

#### Example

```
[TESTPORT_PARAMETERS]
mtc.*.LocalIPAddress := "164.48.161.146"
"Alma-Ata".RemoteIPAddress := "164.48.161.147"
mtc.RADIUS[0].LocalUDPPort := "12345"
mtc.RADIUS[1].LocalUDPPort := "12346"
system.MySystemInterface1.RemoteIPAddress := "10.1.1.1"
system.MySystemInterface2.RemoteIPAddress := "10.1.1.2"
```

## 7.4 [DEFINE]

In this section you can create macro definitions that can be used in other configuration file sections except [INCLUDE]. This way if the same value must be given several times in the configuration file, you can make a definition for it and only refer to the definition later on. In case of a change, you wouldn't need to change the values all over the configuration file, but only in the definition.

This section may contain zero, one or more macro definitions (assignments). Each macro definition consists of a macro identifier, which shall be a TTCN-3 identifier, an assignment operator and the macro value. The macro value is either a simple or a structured value (see the BNF below).

The simple macro value is a sequence of one or more literal values and macro references. The elements of the sequence must not be separated by anything, whitespaces or comments are not allowed.

The structured macro value can be used to define instances of complex TTCN-3 data structures. The defined values can be assigned to compound module parameters. There are two restrictions regarding the syntax of this value. The first and last character of the value are '{' and '}'. The value must be well-formed regarding the curly brackets. Every value which satisfies these two rules is accepted as a macro definition. Please note that macro definitions do not have a type. The defined values are copied to the place of the macro references. The semantic correctness is determined by the context of the macro reference (see the examples section).

Macro references can refer to previously defined macros. The reference can be provided in the following 3 formats which have the same meaning:

- \$macroname

Prepared (Subject resp) ETHBAAT Jenő Balasko		No. 2/198 17-CRL 113 200/5 Uen		
Approved (Document resp) ETHLEL Elemer Lelik	Checked ETHGRY	Date 2015-05-15	Rev C	Reference

- `${macroname}`
- `${macroname,charstring}`

The above 3 different notations can also be used in other sections to refer to the macro with name “macroname”.

The literal value can be either a word (a sequence of arbitrary characters except whitespace) or a character string value delimited by quotation marks. The latter form is useful when the macro value is an empty string or contains whitespace characters. Literal values cannot follow each other, only macro references can.

The values of macros as well as environmental variables set in the shell can be expanded in the configuration file using a special syntax described below. If both a macro and an environment variable are defined with the same name the macro of the configuration file has the precedence. If neither exists an error message is reported. It is possible to assign value to the same macro identifier more than once, in this case the last assignment will determine the value of the macro. When assigning a new value to the same macro, it is also possible to use the macro’s previous value.

In parallel mode, in order to ensure the consistency of the test system, all macro substitutions are performed in the Main Controller. Hence the settings of environment variables are inherited from the shell that the Main Controller was started from.

Macro definitions of this section do not change the environment space maintained by the operating system in any process. Thus, the macros defined in this section are not visible by the system call `getenv(3)` issued in test ports or external functions.

Macro references can have one of these two formats:

- Simple reference:  
a dollar character followed immediately by the macro identifier.  
Example: `$macroName`. In this case the value of the definition will be inserted as a literal charstring value.
- Modified reference:  
a dollar character followed by a pair of curly brackets containing the macro identifier and a modifier separated by a comma.  
Example: `${macroName, modifier}`. Whitespaces are allowed within the pair of brackets, but the opening bracket must follow the dollar character immediately. In this case the type of the substituted token is specified by the modifier. Before substitution it is verified whether the value of the referred macro or environment variable fulfills the requirements for the given modifier.

The following modifiers are available for macro substitution:

Prepared (Subject resp) ETHBAAT Jeno Balasko		No. 2/198 17-CRL 113 200/5 Uen		
Approved (Document resp) ETHLEL Elemer Lelik	Checked ETHGRY	Date 2015-05-15	Rev C	Reference

- `integer`  
Transforms the value of the macro into an integer value. The macro value may contain decimal numbers only (leading and trailing whitespaces are not allowed).
- `float`  
Transforms the value of the macro into a value of type float. The substitution is possible only if the value is an integer or a floating point number.
- `boolean`  
Transforms the value of the macro into a boolean value. The macro value shall contain the word true or false.
- `bitstring`  
Transforms the value of the macro into a literal bitstring value. Only binary digits are allowed in the macro value.
- `hexstring`  
Transform the value of the macro into a hexstring value. Only hexadecimal digits are allowed in the macro value.
- `octetstring`  
Transforms the value of the macro into an octetstring. The macro value shall contain even (including zero) number of hexadecimal digits.
- `charstring`  
Transforms the value of the macro into a literal value of type charstring. There is no restriction about the contents of the macro value. Note: The reference with this modifier has the same result as a simple reference.
- `binaryoctet`  
Transforms the value of the macro into an octetstring value so that the octets of the resulting string will contain the ASCII character code of the corresponding character from the macro value. The macro value to be substituted may contain any kind of character.
- `identifier`  
Transforms the value of the macro into a TTCN–3 identifier. This modifier is useful, for instance, for specifying values of enumerated types in section [MODULE\_PARAMETERS]. The macro value shall contain a valid TTCN–3 identifier. Leading and trailing whitespace characters are not allowed in the macro value.
- `hostname`  
Transforms the value of the macro into a host name, DNS name or IPv4 or IPv6 address. The modifier can be used in sections [GROUPS], [COMPONENTS] and [MAIN\_CONTROLLER]. The value to be substituted shall contain a valid host name, DNS name or IP address formed from alphanumerical, dash (-), underscore (\_), dot (.), colon(:)

Prepared (Subject resp) ETHBAAT Jeno Balasko		No. 2/198 17-CRL 113 200/5 Uen		
Approved (Document resp) ETHLEL Elemer Lelik	Checked ETHGRY	Date 2015-05-15	Rev C	Reference

or percentage (%) characters. Leading and trailing whitespace is not allowed.

#### 7.4.1 BNF Productions for this Section

```
DefineSection ::= "[DEFINE]" {DefinitionAssignment}  
DefinitionAssignment ::= Identifier AssignmentChar DefinitionRValue  
DefinitionRValue ::= SimpleValue | StructuredValue  
SimpleValue ::= {Word | String | IPaddress | MacroReference}  
StructuredValue ::= "{" { {SimpleValue} | StructuredValue } "}"  
| "{" "}"
```

Word may contain numbers, letters and other non-whitespace characters mixed in any way.

Prepared (Subject resp) ETHBAAT Jeno Balasko		No. 2/198 17-CRL 113 200/5 Uen		
Approved (Document resp) ETHLEL Elemer Lelik	Checked ETHGRY	Date 2015-05-15	Rev C	Reference

**Example**

```
[DEFINE]
localhost := 127.0.0.1
binary_240 := 11110000
four := 4.0
LongString := "This is a very long string."
x1 = "Connecting to "${localhost}
x2 = $LongString${localhost,charstring}" is an IP address"
binary_str := ${binary_240}010101

/* Examples for the structured macro definitions */
// on the left side of the arrow is the definition
// the substituted value is on the right side
DEF_20 := 1 // 1
DEF_21 := "1" // 1
DEF_22 := "\"1\"" // "1"
DEF_23 := a // a
DEF_24 := "a" // a
DEF_25 := "\"a\"" // "a"

DEF_30 := { f1 := ${DEF20}} // => DEF_30 := { f1 := 1}
DEF_31 := { f1 := ${DEF21}} // => DEF_31 := { f1 := 1}
DEF_32 := { f1 := ${DEF22}} // => DEF_32 := { f1 := "1"}
DEF_33 := { f1 := ${DEF23}} // => DEF_33 := { f1 := a}
DEF_34 := { f1 := ${DEF24}} // => DEF_34 := { f1 := a}
DEF_35 := { f1 := \"${DEF24}\"} // => DEF_35 := { f1 := "a"}
DEF_36 := { f1 := ${DEF25}} // => DEF_36 := { f1 := "a"}
DEF_37 := { f1 := a} // => DEF_37 := { f1 := a}
DEF_38 := { f1 := "a"} // => DEF_38 := { f1 := "a"}
DEF_39 := { f1 := "${DEF_20}"} // => DEF_39 := { f1 := "${DEF_20}"}
// DEF_30 and DEF_31 are valid module parameter definitions for tsp_1
// the other definitions are not valid for tsp_1 (see section Error! Reference source not found.)

DEF_40 := { f2 := ${DEF20}} // => DEF_40 := { f2 := 1}
DEF_41 := { f2 := ${DEF21}} // => DEF_41 := { f2 := 1}
DEF_42 := { f2 := ${DEF22}} // => DEF_42 := { f2 := "1"}
DEF_43 := { f2 := ${DEF23}} // => DEF_43 := { f2 := a}
DEF_44 := { f2 := ${DEF24}} // => DEF_44 := { f2 := a}
DEF_45 := { f2 := \"${DEF24}\"} // => DEF_45 := { f2 := "a"}
DEF_46 := { f2 := ${DEF25}} // => DEF_46 := { f2 := "a"}
DEF_47 := { f2 := a} // => DEF_47 := { f2 := a}
DEF_48 := { f2 := "a"} // => DEF_48 := { f2 := "a"}
DEF_49 := { f2 := "${DEF_20}"} // => DEF_49 := { f2 := "${DEF_20}"}
// DEF_{42|45|46|48|49} are valid module parameter definitions for tsp_1
// the other definitions are not valid for tsp_1 (see section Error! Reference source not found.)

// complex data structures can also be referenced
DEF_50 := { f1 := ${DEF_42}, f2 := "a"}
```

**Use example:**

```
[MODULE_PARAMETERS]
par1 := $localhost // "127.0.0.1"
par2 := ${binary_240, bitstring} // '11110000'B
par3 := ${binary_240, hexstring} // '11110000'H
par4 := ${four, float} // 4.0
par5 := ${four, binaryoctet} // '342E30'O
par6 := ${LongString, identifier} // ERROR: invalid substitution
par7 := "$myVariable" // substitution is not done
[MAIN_CONTROLLER]
LocalAddress = ${localhost, hostname} // 127.0.0.1
```

The tokens substituted are given in comments.

Prepared (Subject resp) ETHBAAT Jeno Balasko		No. 2/198 17-CRL 113 200/5 Uen		
Approved (Document resp) ETHLEL Elemer Lelik	Checked ETHGRY	Date 2015-05-15	Rev C	Reference

### *TTCN file example*

```
// ttcn
module a {
  modulepar Rec tsp_1;
  modulepar Rec2 tsp_1;
  type record Rec {
    integer f1 optional, charstring f2 optional
  }
  type record Rec2 {
    Rec f1 optional, charstring f2 optional
  }
}
```

## 7.5 [INCLUDE]

It is possible to use configuration settings (module parameters, test port parameters, etc.) given in other configuration files, the configuration files just need to be listed in this section, with their full or relative pathnames. To the host controllers it will look like as if the configuration files would have been merged together into one configuration file.

Each included file shall form a valid configuration file with complete section(s). The [INCLUDE] directives of included files are processed recursively. Each referenced configuration file is processed exactly once even if it is included from several places. Relative pathnames are resolved based on the directory of the referring configuration file.

### 7.5.1 BNF Productions for this Section

```
IncludeSection ::= "[INCLUDE]" {IncludeFile}
IncludeFile ::= Cstring
```

The file's name is a character string, given between quotation marks.

#### *Example*

```
[INCLUDE]
"base_definitions.cfg"
"../additional_parameters.cfg"
```

## 7.6 [ORDERED\_INCLUDE]

It is possible to include configuration files to a specific location using the [ORDERED\_INCLUDE] section. The included file can be given with the same syntax as in the [INCLUDE] section. The file can be specified with an absolute path, or a path relative to the configuration file in which the [ORDERED\_INCLUDE] section takes place. Relative pathnames are resolved based on the directory of the referring configuration file.

Each included file shall form a valid configuration file with complete section(s). Circular imports are not accepted.

Prepared (Subject resp) ETHBAAT Jeno Balasko		No. 2/198 17-CRL 113 200/5 Uen		
Approved (Document resp) ETHLEL Elemer Lelik	Checked ETHGRY	Date 2015-05-15	Rev C	Reference

### 7.6.1 BNF Productions for this Section

```
OrderIncludeSection ::= "[ORDERED_INCLUDE]" {IncludeFile}  
IncludeFile ::= Cstring
```

The file's name is a character string, given between quotation marks.

#### Example

```
// main.cfg  
[ORDERED_INCLUDE]  
  
"oi.cfg"  
  
"oi2.cfg"  
[MODULE_PARAMETERS]  
tsp_1 := 3  
  
// oi.cfg  
[MODULE_PARAMETERS]  
tsp_1 := 1  
  
// oi2.cfg  
[MODULE_PARAMETERS]  
  
tsp_1 := 2
```

In this example we have 3 configuration files. The names of the files are included as comments. The ETS will be started with the first one ("main.cfg"). This configuration file includes "oi.cfg" and "oi2.cfg". The included files are processed sequentially. The first included file ("oi.cfg") will set the module parameter "tsp\_1" to 1. As the processing continues, the second included file ("oi2.cfg") will set it to 2. Finally when the included files are processed, the main configuration file sets it to 3. In this case, the module parameter named tsp\_1 will have the final value of 3.

## 7.7 [EXTERNAL\_COMMANDS]

This section defines external commands (shell scripts) to be executed by the ETS whenever a control part or test case is started or terminated. Using this feature you can control external monitor programs (like `tcpdump` in case of IP testing) automatically during test execution. In case of parallel mode, the external command is executed on the host where the MTC runs. The name of the corresponding module or test case is passed to the external command as argument. For `BeginTestCase` and `EndTestCase` the name of the module and test case separated with a dot is passed as argument; and additionally the test case verdict for `EndTestCase`. For example, this allows you to collect the output of `tcpdump` in separate files for each test case where the file name contains the name of the test case.

Prepared (Subject resp) ETHBAAT Jenő Balasko		No. 2/198 17-CRL 113 200/5 Uen		
Approved (Document resp) ETHLEL Elemer Lelik	Checked ETHGRY	Date 2015-05-15	Rev C	Reference

All commands are optional and can be set independently. The command name (or full path) must be given within double quotes. Whitespaces and special characters are treated as part of the command name and will not be interpreted by the shell. This means that additional, fixed, arguments can not be passed to the external command. If the command string is empty no command will be executed (it also clears the command that was set previously).

### 7.7.1 BNF Productions for this Section

```
ExternalCommandsSection ::= "[EXTERNAL_COMMANDS]" {ExternalCommand}
ExternalCommand ::= CommandType AssignmentChar Command [SemiColon]
CommandType ::= "BeginControlPart" | "EndControlPart" | "BeginTestCase" |
               "EndTestCase"
Command ::= StringValue
```

#### Example

```
[EXTERNAL_COMMANDS]
BeginTestCase := "/usr/local/tester/bin/StartTcpdump"
EndTestCase := "/usr/local/tester/bin/StopTcpdump"
BeginControlPart := "this will be overwritten"
EndControlPart := ""
```

### 7.7.2 Example: Running tcpdump during test execution

In case of testing IP based protocols it might be useful to monitor the network during TTCN-3 test execution. The following shell scripts show an example how to start the program `tcpdump` in the background at the beginning of every test case and how to terminate it when a test case is finished.

When `tcpdump` is running, its `pid` is stored in the file `/etc/tcpdump.pid` to inform the stopping script which process to kill. Of course, the command line options for `tcpdump` may be changed to fit your needs. The output of `tcpdump` is saved in the file `<testcase name>.dump` in the working directory of the executable test program, which is useful when `repgen` is used after test execution.

To make this working, you should give the names or full pathes of these scripts as `BeginTestCase` and `EndTestCase` in section `[EXTERNAL_COMMANDS]` of the configuration file.

A complete example script for starting `tcpdump`:

```
#!/bin/sh

PIDFILE=/tmp/tcpdump.pid

if [ -e $PIDFILE ]
then
    kill `cat $PIDFILE`
    rm $PIDFILE
fi

/usr/local/sbin/tcpdump -e -n -s 200 -x -v -i eth1 ip6 >$1.dump \
2>/dev/null &
PID=$!

echo $PID >$PIDFILE
```

Prepared (Subject resp) ETHBAAT Jeno Balasko		No. 2/198 17-CRL 113 200/5 Uen		
Approved (Document resp) ETHLEL Elemer Lelik	Checked ETHGRY	Date 2015-05-15	Rev C	Reference

The script for stopping tcpdump:

```
#!/bin/sh

PIDFILE=/tmp/tcpdump.pid

if [ -e $PIDFILE ]
then
    kill `cat $PIDFILE`
    rm $PIDFILE
fi
```

## 7.8 [EXECUTE]

In this section you have to specify what parts of your test suite you want to execute. In single mode the configuration file is useless without this section. The section [EXECUTE] is optional in parallel mode. If it is missing, You shall start testcases manually from command line with the command `smtc [module name|.control|.testcase name|. *]]` see UG [17] 4.4.2.1. In this case a parameter after `smtc` is mandatory. Don't omit this section in case of using `ttcn3_start`, otherwise no testcase will be executed.

You can start TTCN-3 module control parts and test cases individually. There is one limitation: only those test cases having no parameters, or only parameters with default values, can be executed from this section. Other test cases can be started from the module control part with proper actual parameters.

In this section, a single identifier (or an identifier followed by the optional suffix `.control`) means the control part of that TTCN-3 module. Test case names shall be preceded by the name of module that they can be found in and a dot character. You can use the character asterisk (\*) instead of test case name, which means the execution of all test cases of the corresponding module in the same order as they are defined in the TTCN-3 source code.

The control parts and test cases are executed in the same order as you specified them in this section. If you define the same module or test case name more than once, that control part or test case will be executed, of course, many times.

### 7.8.1 The BNF Specification of this Section

```
ExecuteSection ::= "[EXECUTE]" {ExecuteItem}

ExecuteItem ::= (ControlPart | TestCase) [SemiColon]

ControlPart ::= ModuleName [ "." "control" ]

ModuleName ::= Identifier

TestCase ::= ModuleName "." TestCaseName

TestCaseName ::= Identifier | ""
```

Prepared (Subject resp) ETHBAAT Jeno Balasko		No. 2/198 17-CRL 113 200/5 Uen		
Approved (Document resp) ETHLEL Elemer Lelik	Checked ETHGRY	Date 2015-05-15	Rev C	Reference

### Example

```
[EXECUTE]
IPv6Demo.send_echo
IPv6Demo.send_echo // run it twice
IPv6BaseSpecification
IPv6NeighborDiscovery.*
```

## 7.9 [GROUPS] (Parallel mode)

In this section you can specify groups of hosts. These groups can be used inside the [COMPONENTS] section to restrict the creation of certain PTCs to a given set of hosts. See also section [7.10](#).

This section contains any number of group specifications in the following form: group name, assignment operator (:=) and either an asterisk (\*) or a comma-separated list of host names (DNS names) or IP addresses in which you should enlist each hosts belonging to that group. The asterisk appearing on the right side denotes all hosts that take part in the test execution.

Groups may overlap, that is, the same hosts can belong to several groups. Group references, however, cannot appear on the right side. It is worth mentioning that group names are case sensitive.

NOTE: The groups defined in this section have nothing to do with TTCN-3 group of definitions construct!

### 7.9.1 The BNF Specification of this Section

```
GroupsSection ::= "[GROUPS]" {GroupItem}

GroupItem ::= GroupName AssignmentChar (GroupMemberList | "**") [SemiColon]

GroupName ::= Identifier

GroupMemberList ::= GroupMember {"," GroupMember}

GroupMember ::= HostName | IPAddress
```

### Example

```
[GROUPS]
HeintelAndPauler := heintel, pauler.eth.ericsson.se
myGroup := 153.44.87.34, test-host.123.com
AllHosts := *
```

Prepared (Subject resp) ETHBAAT Jeno Balasko		No. 2/198 17-CRL 113 200/5 Uen		
Approved (Document resp) ETHLEL Elemer Lelik	Checked ETHGRY	Date 2015-05-15	Rev C	Reference

## 7.10 [COMPONENTS] (Parallel mode)

This section consists of rules restricting the location of created PTCs. These constraints are useful when distributed tests are executed in a heterogeneous environment. The participating computers may have different hardware setup, computing capacity or operating system. Thus some physical interfaces or Test Ports might be present only on a part of the hosts<sup>30</sup>.

The rules are described in form of assignments. The left side contains a component identifier while the right side names a host or a group of hosts on which the given components are executed. The components can be selected by their component type or name assigned in create operations. The component identifiers are case sensitive. The assigned hosts are taken from the corresponding host group set from the section [GROUPS] (Section [7.9](#)).

Each component type or component name can appear in at most one rule. The asterisk (\*) stands for all component identifiers that do not appear in any rule. The asterisk can show in a single rule only.

When a TTCN-3 parallel test component is being created it is the responsibility of the MC to choose a suitable and available<sup>31</sup> host for it. First a subset of available hosts, the set of so-called candidates, is determined based on the component distribution rules. The MC implements a load balancing algorithm so that the location of the component will be the candidate with the smallest load, that is, the least number of active TTCN-3 test components<sup>32</sup>. Once a component is assigned to a host it, cannot be moved to another one later during its life.

If a newly created PTC matches more than one rule (because both its component type and name is found in the section) all available members of both assigned groups are considered to be candidates.

If section [COMPONENTS] is empty or omitted from the configuration file all available hosts are considered to be candidates. If the calculated set of candidates is an empty set (i.e. there is no available host that is allowed by the rules) the create operation will fail and dynamic test case error will occur on the ancestor component.

If the location of the PTC is explicitly specified in the create operation (see section [3.8](#) for the syntax of this language extension) the rules of this section are ignored. In this case the set of candidates is determined based on the host name or group name that was specified as location.

<sup>30</sup> On the remaining computers the unsupported Test Ports shall be substituted with empty stubs (i.e. generated and unmodified skeletons).

<sup>31</sup> Only those hosts participate in the component distribution algorithm that have an active HC, which has been started by the user. MC ignores all unavailable group members silently and will not start the HC on them.

<sup>32</sup> This term of load has no direct relation to the load average calculated by UNIX kernels.

Prepared (Subject resp) ETHBAAT Jeno Balasko		No. 2/198 17-CRL 113 200/5 Uen		
Approved (Document resp) ETHLEL Elemer Lelik	Checked ETHGRY	Date 2015-05-15	Rev C	Reference

### 7.10.1 The BNF Specification of this Section

```
ComponentsSection ::= "[COMPONENTS]" {ComponentItem}
```

```
ComponentItem ::= ComponentId AssignmentChar ComponentLocation [SemiColon]
```

```
ComponentId ::= Identifier | "*"
```

```
ComponentLocation ::= GroupName | HostName | IPAddress
```

#### Example

```
[COMPONENTS]  
MyComponentType := HeintelAndPauler  
CPComponentType := 153.44.87.34  
* := AllHosts
```

## 7.11 [MAIN\_CONTROLLER] (Parallel mode)

The options herein control the behavior of MC. The section [MAIN\_CONTROLLER] includes four options to be set.

Options `LocalAddress` and `TCPPort` determine the IP address and TCP port on which the MC application will listen for incoming HC connections. Setting `LocalAddress` can be useful on computers having multiple local IP addresses (multi-homed hosts). The value of `LocalAddress` can be either an IP address or a DNS name, which must resolve to an address that belongs to a local network interface. If this option is omitted MC will accept connections on all local IP addresses.

The value of option `TCPPort` is an integer number between 0 and 65535. The recommended port number is 9034. Using a TCP port number that is less than 1024 may require super-user (root) privileges. The MC will listen on an ephemeral port chosen by the kernel when `TCPPort` is omitted or set to zero.

The optional variable `NumHCs` provides support for automated (batch) execution of distributed tests. When present, the MC will not give a command prompt, but wait for `NumHCs` HCs to connect. When the specified number of HCs are connected, the MC automatically creates MTC and executes all items of the section [EXECUTE] (see section 7.8). When finished, the MTC is terminated and the MC quits automatically. If `NumHCs` was omitted then the MC shall be controlled interactively, that is, you have to issue the commands `cmtc` and `smtc` yourself (see also sections 12.3, 12.3.1 of the TITAN User Guide [\[13\]](#)).

Prepared (Subject resp) ETHBAAT Jeno Balasko		No. 2/198 17-CRL 113 200/5 Uen		
Approved (Document resp) ETHLEL Elemer Lelik	Checked ETHGRY	Date 2015-05-15	Rev C	Reference

The `KillTimer` option tells the MC to wait some seconds for a busy test component (MTC or PTC) to terminate when it was requested to stop<sup>33</sup>. The MC in co-operation with the local HC kills the UNIX process if the component did not terminate properly before `KillTimer` expiry. The purpose of this function is to prevent the test system from deadlocks. Please note that when the UNIX process of MTC is killed all existing PTCs are destroyed at the same time.

The value of `KillTimer` is measured in seconds and can be given in either integer or floating point notation. Setting `KillTimer` to zero disables the kill functionality, that is, busy test components will not be killed even if they do not respond within a very long time period. When omitted, the default value of `KillTimer` is 10 seconds. This value is sufficient in typical test setups, but it needs to be increased on heavily loaded computers (e.g. when running performance tests). Setting a too short `KillTimer` value may have undesired effects as the final verdict of killed PTCs, which is not known by MC, is always substituted by error.

### 7.11.1

#### The BNF Specification of this Section

```
MainControllerSection ::= "[MAIN_CONTROLLER]" {MainControllerAssignment}
MainControllerAssignment ::= (LocalAddress | TCPPort | NumHCs | KillTimer |
    UnixSocketsEnabled) [SemiColon]
LocalAddress ::= "LocalAddress" AssignmentChar (HostName | IPAddress)
TCPPort ::= "TCPPort" AssignmentChar IntegerValue
NumHCs ::= "NumHCs" AssignmentChar IntegerValue
KillTimer ::= "KillTimer" AssignmentChar (IntegerValue | FloatValue)
UnixSocketsEnabled ::= "UnixSocketsEnabled" AssignmentChar ("Yes" | "No")
```

#### Example:

```
[MAIN_CONTROLLER]
LocalAddress := 192.168.1.1
TCPPort := 9034
NumHCs := 3
KillTimer := 4.5
UnixSocketsEnabled := Yes
```

## 7.12

### [PROFILER]

The settings in this section control the behavior of the TTCN-3 Profiler. These settings only affect the TTCN-3 modules specified in the file list argument of the compiler option `-z`. If this compiler option is not set, then the `[PROFILER]` section is ignored.

### 7.12.1

#### Enabling and disabling features

The following features can be enabled or disabled through the configuration file:

<sup>33</sup> The MTC can be terminated from the MC's user interface or from a PTC by executing the `mtc.stop` operation. The termination of a PTC can be requested either explicitly (using a TTCN-3 component `stop` or `kill` operation) or implicitly (at the end of test case).

Prepared (Subject resp) ETHBAAT Jeno Balasko		No. 2/198 17-CRL 113 200/5 Uen		
Approved (Document resp) ETHLEL Elemer Lelik	Checked ETHGRY	Date 2015-05-15	Rev C	Reference

- `DisableProfiler` – if set to `true`, the measurement of execution times is disabled and data related to execution times or average times will not be present in the statistics file. Default value: `false`
- `DisableCoverage` – if set to `true`, the execution count of code lines and functions is not measured and data related to execution counts, average times or unused lines/functions will not be present in the statistics file. Default value: `false`
- If both `DisableProfiler` and `DisableCoverage` are set to `true`, then the profiler acts as if it wasn't activated in any of the modules (as if the compiler flag `-z` was not set). The database and statistics files are not generated.
- `AggregateData` – if set to `true`, the data gathered in the previous run(s) is added to the current data, otherwise all previous data is discarded, default value: `false`
- `DisableStatistics` – if set to `true`, the statistics file will not be generated at the end of execution, default value: `false`
- `StartAutomatically` – if set to `true`, the profiler will start when the program execution starts, otherwise it will only start at the first `@profiler.start` command (it needs to be started individually for each component in parallel mode), default value: `true`
- `NetLineTimes` – if set to `true`, the execution times of function calls will not be added to the caller lines' total times, default value: `false`
- `NetFunctionTimes` – if set to `true`, the execution times of function calls will not be added to the caller functions' total times, default value: `false`

### 7.12.2 Setting output files

The `DatabaseFile` setting can be used to specify the name and path of the database file (as a string with double quotation marks, like a `charstring`). This is the file imported by the profiler if data aggregation is set (if this setting is changed between runs, the profiler will not find the old database).

Default value: `profiler.db`

Similarly the `StatisticsFile` setting can be used to specify the name and path of the statistics file.

Default value: `profiler.stats`

Prepared (Subject resp) ETHBAAT Jenö Balasko		No. 2/198 17-CRL 113 200/5 Uen		
Approved (Document resp) ETHLEL Elemer Lelik	Checked ETHGRY	Date 2015-05-15	Rev C	Reference

### 7.12.3 Statistics filters

The `StatisticsFilter` setting can be used to specify which lists will be calculated and displayed in the statistics file. Its value is a list of filters separated by ampersands (&). Vertical lines (|) can also be used to separate the filters (as if they were bits added together with binary or) to the same effect.

The concatenation mark (&=) can also be used with this setting to specify the filters in multiple commands.

The filters can also be specified with hexadecimal values (similarly to `hexstrings`, but without the quotation marks and the `H` at the end).

Table 25 Statistics filters, single lists

Filter	Numeric value	Represented list
NumberOfLines	0x00000001	Number of code lines and functions
LineDataRow	0x00000002	Total time and execution count of code lines (raw)
FuncDataRow	0x00000004	Total time and execution count of functions (raw)
LineAvgData	0x00000008	Average time of code lines (raw)

Top10FuncData	0x00540000	Total time, execution count and average time of functions (sorted, total, top 10 only)
Top10AllData	0x007E0000	Total time, execution count and average time of code lines and functions (sorted, total, top 10 only)
UnusedData	0x01800000	Unused code lines and functions
All	0x01FFFFFF	All lists

Prepared (Subject resp) ETHBAAT Jenő Balasko		No. 2/198 17-CRL 113 200/5 Uen		
Approved (Document resp) ETHLEL Elemer Lelik	Checked ETHGRY	Date 2015-05-15	Rev C	Reference

Note: the DisableProfiler and DisableCoverage settings also influence which lists are displayed in the statistics file (e.g.: if DisableCoverage is set to true and StatisticsFilter is set to Top10LineData, then the statistics file will only contain the top 10 total times list).

#### 7.12.4

#### The BNF Specification of this Section

```
ProfilerSection ::= "[PROFILER]" {ProfilerSetting}
ProfilerSetting ::= (DisableProfilerSetting | DisableCoverageSetting |
    DatabaseFileSetting | AggregateDataSetting | StatisticsFileSetting |
    DisableStatisticsSetting | StatisticsFilterSetting) [SemiColon]
DisableProfilerSetting ::= "DisableProfiler" AssignmentChar BooleanValue
DisableCoverageSetting ::= "DisableCoverage" AssignmentChar BooleanValue
DatabaseFileSetting ::= "DatabaseFile" AssignmentChar CharstringValue
AggregateDataSetting ::= "AggregateData" AssignmentChar BooleanValue
StatisticsFileSetting ::= "StatisticsFile" AssignmentChar CharstringValue
DisableStatisticsSetting ::= "DisableStatistics" AssignmentChar BooleanValue
StatisticsFilterSetting ::= "StatisticsFilter" (AssignmentChar | ConcatChar)
    StatisticsFilter [ { ("&" | "|") StatisticsFilter } ]
StatisticsFilter ::= ("NumberOfLines" | "LineDataRow" | "FuncDataRow" |
    "LineAvgRaw" | "FuncAvgRaw" | "LineTimesSortedByMod" | "FuncTimesSortedByMod" |
    "LineTimesSortedTotal" | "FuncTimesSortedTotal" | "LineCountSortedByMod" |
    "FuncCountSortedByMod" | "LineCountSortedTotal" | "FuncCountSortedTotal" |
    "LineAvgSortedByMod" | "FuncAvgSortedByMod" | "LineAvgSortedTotal" |
    "FuncAvgSortedTotal" | "Top10LineTimes" | "Top10FuncTimes" | "Top10LineCount" |
    "Top10FuncCount" | "Top10LineAvg" | "Top10FuncAvg" | "UnusedLines" |
    "UnusedFunc" | {Hex}+)
```

#### Example:

```
[PROFILER]
DisableProfiler := false
DisableCoverage := false
DatabaseFile := "data.json"
AggregateData := false
StatisticsFile := "prof.stats"
DisableStatistics := false
StatisticsFilter := Top10AllData & UnusedData
StatisticsFilter &= AllRawData
StatisticsFilter &= 88A0
```

#### 7.13

#### Dynamic Configuration of Logging Options

Some logging options may be altered during the run of the test suite. This allows e.g. to vary the logging verbosity between testcases.

The interface is contained in `$(TCN3_DIR)/include/TitanLoggerControl.ttcn`; this file needs to be added to the project. `TitanLoggerControl.ttcn` contains definitions of various external functions which can be called from TTCN-3 code. The implementation of these external functions is built into the Titan runtime library; it will be linked automatically.

The individual logging severities are contained in the "Severity" enumerated type. A logging mask is represented by a record-of:

```
type record of Severity Severities;
```

For each logging bit set, the record-of will contain an element.

Prepared (Subject resp) ETHBAAT Jeno Balasko		No. 2/198 17-CRL 113 200/5 Uen		
Approved (Document resp) ETHLEL Elemer Lelik	Checked ETHGRY	Date 2015-05-15	Rev C	Reference

The TitanLoggerControl module defines several constants:

```
const Severities log_nothing      := {};  
const Severities log_console_default := { ... }  
const Severities log_all := { ... } // LOG_ALL, without MATCHING, DEBUG  
const Severities log_everything := { ... } // really everything
```

These constants can be used when setting logger options.

Each function has a parameter named `plugin`, to specify which plugin is being manipulated. Currently, the value of the `plugin` parameter must be "LegacyLogger".

### 7.13.1 Retrieving Logging Masks

The following functions can be used to retrieve the current value of the logger file mask/console mask:

```
get_file_mask(in charstring plugin) return Severities;  
get_console_mask(in charstring plugin) return Severities;
```

### 7.13.2 Setting Logging Masks

The following functions set the file mask or console mask, overwriting the previous value:

```
set_file_mask(in charstring plugin, in Severities s);  
set_console_mask(in charstring plugin, in Severities s);
```

Logging severities present in the parameter will be switched on; severities absent from the parameter will be switched off.

The following functions allow adding individual Severity values to the list of events that are logged, without affecting other severities:

```
add_to_file_mask(in charstring plugin, in Severities s);  
add_to_console_mask(in charstring plugin, in Severities s);
```

Logging severities present in the parameter will be switched on; severities absent from the parameter will not be modified. Example: to turn on `DEBUG_ENCDEC` without affecting other severities:

```
var Severities encdec := { DEBUG_ENCDEC }  
TitanLoggerControl.add_to_file_mask("LegacyLogger", encdec);
```

Please note that each bit is treated individually. To turn on a first level category, one needs to enumerate all subcategories. For example, to turn on all `DEBUG` messages, the value of the `Severities` variable should be:

Prepared (Subject resp) ETHBAAT Jeno Balasko		No. 2/198 17-CRL 113 200/5 Uen		
Approved (Document resp) ETHLEL Elemer Lelik	Checked ETHGRY	Date 2015-05-15	Rev C	Reference

```
var Severities debug_all := { DEBUG_ENCDEC, DEBUG_TESTPORT, DEBUG_UNQUALIFIED
};
TitanLoggerControl.add_to_file_mask("LegacyLogger", debug_all);
```

The following functions allow removing of individual Severities:

```
remove_from_file_mask(in charstring plugin, in Severities s);
remove_from_console_mask(in charstring plugin, in Severities s);
```

Logging severities present in the parameter will be switched off; severities absent from the parameter will not be modified.

When setting file/console masks, redundant severity values are ignored. For example, the two following values have the same effect when passed to set\_file\_mask.

```
var Severities ptc := { PARALLEL_PTC };
var Severities ptc3:= { PARALLEL_PTC, PARALLEL_PTC, PARALLEL_PTC };
```

### 7.13.3 Manipulating the Log File Name

The following function allows setting the log file name skeleton. See section 7.2.3 for possible values.

```
set_log_file(in charstring plugin, in charstring filename);
```

### 7.13.4 Enabling/disabling the Logging of TTCN-3 Entity Name

The following functions allow the reading and writing of the LogEntityName parameter (section 7.2.11 above)

```
set_log_entity_name(in charstring plugin, in boolean b);
get_log_entity_name(in charstring plugin) return boolean;
```

## 8 The TITAN Project Descriptor File

Concept of the project is defined in chapter 4 of User Guide for the TITAN Designer [17] because it is introduced in TITAN Designer which is the name of one of the Eclipse plugin of TITAN.

The content of a project and all project specific settings are described in the TITAN project descriptor (TPD) file. The name of the TPD file is in the form <project\_name>.tpd e.g. HelloTitan.tpd.

The tpd file contains information about the project name, the contained files, referenced (used) projects, make, configuration and running information etc. (se later) but doesn't contain source files at all.

Tpd files are designed to produce portability for projects. Primarily it is automatically created by the Titan Designer (in Eclipse) when project settings of an existing project are exported (see Chapter 4.9.4 of [17]). The created TPD file can be used to import the project into another workspace (belonging to the same or to a different user) if the files and projects referred by the TPD are available at the new place ( see Chapter 4.9.5 of [17]). If the project to be exported contains referenced (used) project, then the TITAN project setting of the referenced projects shall be exported previously.

Tpd files can be used without TITAN Designer for example for generating hierarchical Makefiles from command line by the makefile generator (see 6.1.3). The files and TPD files referred by the TPD should be available.

TPD files are designed to be created by the Eclipse Designer but it can be created or modified by experts.

The data is stored in XML format. The schema definition of the project descriptor is delivered with the Titan package and can be found in the \${TTCN3\_DIR}/etc/xsd/TPD.xsd file. If the type of an element is a subtype of string, for example a file name or a path, the xsd file doesn't restrict it but uses only string or NormalizedString as type. Although the compliance of a TPD file for TPD.xsd is a necessary but not sufficient statement, it is very useful to verify the tpd file against TPD.xsd for example with this command:

```
xmllint --noout --schema XSD_FILE XML_FILE
```

Each element is designed to be extendable, so for almost all elements there is a default value defined, if the element is missing this value is used. To simplify the reviews the elements are always saved in an ordered fashion thus limiting the effects of minor changes. The lists can contain from 0 to infinite elements. The O/M column in the tables describes if the element is optional or mandatory.

The TPD file contains a top level element <TITAN\_Project\_File\_Information>.

This has an attribute called "version". This attribute describes the version of the TPD.xsd file which the tpd file validates to. e.g.:

Prepared (Subject resp) ETHBAAT Jeno Balasko		No. 2/198 17-CRL 113 200/5 Uen		
Approved (Document resp) ETHLEL Elemer Lelik	Checked ETHGRY	Date 2015-05-15	Rev C	Reference

<TITAN\_Project\_File\_Information version="1.0">. Currently this version is fixed.

The elements contained in the top level element are listed below in Table .

The content of these elements is discussed later in this chapter.

**Table 27 The sequence of elements of TITAN\_Project\_File\_Information**

Name of the element	Meaning	O/M
ProjectName	The name of the project. This name is used as the name of the TPD file used for export. This is also the name of the project created by TITAN Designer at import. See also chapter 8.1	M
ReferencedProjects	The list of projects referenced by the actual one. Not present if the actual project does not reference any other. See also chapter 8.2	O
Folders	The list of folders present in the project. Not present if the actual project does not contain any folders to be saved. See also chapter 8.3	O
Files	The list of files present in the project. Not present if the actual project does not contain any files to be saved. See also chapter 8.3	O
PathVariables	The list of eclipse path variables active in the workbench. Not present if the actual workbench did not contain any path variables. See also chapter 8.4	O
ActiveConfiguration	The name of the build configuration active whose parameters will be used by TITAN for building the project. See also chapter 8.5	M
Configurations	The list of configurations set on the actual project. Please note, that there is always at least one configuration, the "Default", set for every project. See also chapter 8.6	O
PackedReferencedProjects	PackedReferencedProjects contains not	O

Prepared (Subject resp) ETHBAAT Jenö Balasko		No. 2/198 17-CRL 113 200/5 Uen		
Approved (Document resp) ETHLEL Elemer Lelik	Checked ETHGRY	Date 2015-05-15	Rev C	Reference

	references for other TPDS but the content of the TPDs belonging to the referenced projects (without element PackedReferencedProjects). Not present if the actual project is not referencing any other, or if the saving of this data is not explicitly requested by the user. See also chapter 8.7	
--	--	--

## 8.1 Project Name

The `ProjectName` element contains the name of the project. See also introduction in chapter 8.

Example:

```
<ProjectName>HelloTitan2</ProjectName>
```

## 8.2 Referenced Projects

The `ReferencedProjects` element contains a list of `ReferencedProject` elements, each of which describes a single project referencing relation. A referenced project is a project whose content is used by our project, e.g. its files are imported by the file of the current project.

The following tags are supported:

**Table 28** Attributes of `ReferencedProject`

Name of the attributes	Meaning	O/M
<code>name</code>	The name of the project referenced. Inside eclipse this will create the relation between the actual and the referenced project.	M
<code>projectLocationURI</code>	The path of the project descriptor of the referenced project, relative to the actual descriptor. If the project is not already loaded in eclipse, it will be loaded from this path.	M

Example:

```
<ReferencedProjects>  
  <ReferencedProject name="Hello_world"  
    projectLocationURI="file:../Hello_world/Hello_world.TITAN_Project_Format"=>  
</ReferencedProjects>
```

Prepared (Subject resp) ETHBAAT Jeno Balasko		No. 2/198 17-CRL 113 200/5 Uen		
Approved (Document resp) ETHLEL Elemer Lelik	Checked ETHGRY	Date 2015-05-15	Rev C	Reference

### 8.3 Files and Folders

These elements contain some basic information on files and folders present in the project that is needed to recreate the structure of the project anytime later.

The `Files` element is a list of `FileResource` elements, the `Folders` element is a list of `FolderResource` elements.

Right now the contents of the `FileResource` and `FolderResource` elements are the same. All information is stored in attributes.

**Table 29 The attributes of `FileResource` and `FolderResource`.**

Name of the attribute	Meaning	O/M
<code>projectRelativePath</code>	The path of the resource inside the resource system of eclipse.	M
<code>relativeURI</code>	This is the path relative to the location where the project descriptor files is being saved, in case the path of the resource does not contain any feature, that needs to be resolved, and it is possible to calculate the relative path.  If neither is true, this tag is not present.	O
<code>rawURI</code>	This is the raw path of the resource as stored by the platform. In this form the path variables, or any other feature, are not yet resolved.  If the relative path can not be calculated, this tag is used to provide access to the unprocessed version of the path information. Otherwise missing.	O

If both tags are present the `relativeURI` should be used. It is an error if neither the `relativeURI` nor the `rawURI` attribute is present.

Example:

Prepared (Subject resp) ETHBAAT Jenő Balasko		No. 2/198 17-CRL 113 200/5 Uen		
Approved (Document resp) ETHLEL Elemer Lelik	Checked ETHGRY	Date 2015-05-15	Rev C	Reference

```

<Folders>
  <FolderResource projectRelativePath="src" relativeURI="file:src"/>
  <FolderResource projectRelativePath="virtual" rawURI="virtual:/virtual"/>
</Folders>
<Files>
  <FileResource projectRelativePath=".TITAN_properties"
relativeURI="file:.TITAN_properties"/>
  <FileResource projectRelativePath=".project" relativeURI="file:.project"/>
</Files>

```

## 8.4 Path Variables

The `PathVariables` element stores the list of `PathVariable` elements, each of which describes a single eclipse path variable. They are not used at Makefile generation from command line.

**Table 30 Attributes of PathVariable**

Name of the attribute	Meaning	O/M
Name	The name of the path variable.	M
Value	The value of the path variable.	M

Example:

```

<PathVariables>
  <PathVariable name="path_variable1" value="C:/ekrisza"/>
  <PathVariable name="path_variable2" value="C:/Users/ekrisza/doksi-
workbench-workspace/masik/masik.TITAN_Project_Format"/>
</PathVariables>

```

## 8.5 ActiveConfiguration

The `ActiveConfiguration` element stores the name of the active build configuration whose parameters will be used by TITAN for building the project. Note, this can be overwritten from TITAN Designer (from Eclipse) or from command line generating Makefile(s) by `ttn3_makefilegen` using the `-b` flag, see chapter 6.1.3.

See also chapter 8.6.

Example:

```

<ActiveConfiguration>Default</ActiveConfiguration>

```

## 8.6 Configurations

The `Configurations` element stores a list of `Configuration` elements, each of which describes a single build configuration. Different build configurations can use a different file set, different makefile settings (e.g single or parallel mode, operational system specific settings etc).

The `Configuration` element has a single tag called `name`, and stores the name of the configuration.

Prepared (Subject resp) ETHBAAT Jeno Balasko		No. 2/198 17-CRL 113 200/5 Uen		
Approved (Document resp) ETHLEL Elemer Lelik	Checked ETHGRY	Date 2015-05-15	Rev C	Reference

**Table 31 Elements of Configuration**

Name of the element	Meaning	O/M
ProjectProperties	Stores the settings of the project required to create a Makefile, to build the project, and the project level naming conventions. See chapter 8.6.1.	O
FolderProperties	Stores the properties of each folder contained in the project. Not present if there are no folders in the project, or all folders have all attributes on their default values. See chapter 8.6.2.	O
FileProperties	Stores the properties of each file contained in the project. Not present if there are no files in the project, or all files have all attributes on their default values. See chapter 8.6.3.	O

## 8.6.1 Project Properties

This element contains all information needed to create a proper Makefile for the project to drive the build process (all information other than the list of files) and for naming convention checking. Compare this chapter with chapter “Setting Project Properties” in TITAN Designer Documentation [17].

It can contain 5 elements: MakefileSettings, LocalBuildSettings,

RemoteBuildProperties, NamingConventions,  
ConfigurationRequirements.

Name of the element	Meaning	O/M
MakefileSettings	Stores the settings of the project required to create a Makefile. For more information see 8.6.1.1	O
LocalBuildSettings	Stores the settings of the project required to perform the build. See 8.6.1.2	O
RemoteBuildProperties	Stores information necessary for remote build. See 8.6.1.3	
NamingConventions	Stores the project specific naming conventions. See 8.6.1.4	O
ConfigurationRequirements	Stores the required build configurations of the referenced	O

Prepared (Subject resp) ETHBAAT Jeno Balasko		No. 2/198 17-CRL 113 200/5 Uen		
Approved (Document resp) ETHLEL Elemer Lelik	Checked ETHGRY	Date 2015-05-15	Rev C	Reference

	projects. See 8.6.1.5	
--	-----------------------	--

### 8.6.1.1 Makefile Settings

The flags for the TTCN3 compiler can be specified in this section. For more information please refer to 6.1.1. A supplementary information is placed in brackets.

Useful information can be found in TITAN Designer documentation [17] as well.

**Table 32 The elements of MakefileSettings**

Name	Makefilegen option	Compiler option	Default value (used when not being present)	O/M
generateMakefile (meaningful only in Eclipse)	-	-	true	O
generateInternalMakefile (meaningful only in Eclipse)	-	-	false	O
useAbsolutePath	-a	-	false	O
GNUMake	-g	-	false	O
incrementalDependencyRefresh (meaningful not only in Eclipse, necessary to apply incremental dependency via gnu Make and .d files)	-	-	false	O
functiontestRuntime (use function test runtime (TITAN RUNTIME 2))	-R	-R	false	O
dynamicLinking	-l	-	false	O
singleMode	-s	-	false	O
codeSplitting (select code splitting mode for the generated C++ code)	-U	-U	None	O
defaultTarget ("executable" or "library", if -L applied, see 6.1.2)	-L	-	executable	O

Prepared (Subject resp) ETHBAAT Jeno Balasko		No. 2/198 17-CRL 113 200/5 Uen		
Approved (Document resp) ETHLEL Elemer Lelik	Checked ETHGRY	Date 2015-05-15	Rev C	Reference

targetExecutable	-e	-	N/A	O
TTCN3preprocessor (the name of the preprocessor meaningful only in Eclipse)	-	-	cpp	O
TTCN3preprocessorIncludes	-	-	empty	O
preprocessorIncludes	-p	-	empty	O
disableBER (disable BER encoder/decoder functions)	-	-b	false	O
disableRAW (disable RAW encoder/decoder functions)	-	-r	false	O
disableTEXT (disable TEXT encoder/decoder functions)	-	-x	false	O
disableXER	-	-X	false	O
forceXERinASN.1 (force XER in ASN.1 files)	-	-a	false	O
defaultasOmit (-d compiler option)	-	-d	false	O
enumHackProperty (-E compiler option)	-	-E	false	O
gccMessageFormat (emulate GCC error/warning message format)	-	-g	false	O
lineNumbersOnlyInMessages (use only line numbers in error/warning messages)	-	-i	false	O
includeSourceInfo (include source line info in C++ code)	-	-l	false	O
addSourceLineInfo (add source line info for logging)	-	-L	false	O
suppressWarnings (suppress warnings)	-w	-w	false	O
Quietly (suppress all messages, quiet mode)	-	-q	false	O
namingRules (only in Eclipse)	-	-	unspecified	O
disableSubtypeChecking (disable subtype checking)	-	-y	false	O

Prepared (Subject resp) ETHBAAT Jenő Balasko		No. 2/198 17-CRL 113 200/5 Uen		
Approved (Document resp) ETHLEL Elemer Lelik	Checked ETHGRY	Date 2015-05-15	Rev C	Reference

CxxCompiler (The name of the compiler, only in Eclipse)	-	-	g++	O
optimizationLevel (only in Eclipse)	-	-	"Common optimizations"	O
otherOptimizationFlags (only in Eclipse)	-	-	empty	O
disablePredefinedExternalFolder (only in Eclipse)	-	-	false	O
buildLevel (only in Eclipse, see below and in 6.1.6 The actual building in [17])	-	-	"Level 5 - Creating Executable Test Suite with dependency update"	O
ProjectSpecificRulesGenerator	-	-	Used to place custom rules and new targets into the generated Makefile	O

The supported values of `optimizationLevel` are:

- "None"
- "Minor optimizations"
- "Common optimizations"
- "Optimize for speed"
- "Optimize for size"
- 
- The optimization flags given as the value of `otherOptimizationFlags` are passed to the Cxx compiler.

The support values for `buildLevel` are:

- "Level 0 - Semantic Check"
- "Level 1 - TTCN3 -> C++ compilation"
- "Level 2 - Creating object files"
- "Level 2.5 - Creating object files with heuristical dependency update"
- "Level 3 - Creating object files with dependency update"
- "Level 4 - Creating Executable Test Suite"
- "Level 4.5 - Creating Executable Test Suite with heuristical dependency update"
- "Level 5 - Creating Executable Test Suite with dependency update"

Note that the `targetExecutable` path is stored either relative to the root of the project, or with full path.

Prepared (Subject resp) ETHBAAT Jenő Balasko		No. 2/198 17-CRL 113 200/5 Uen		
Approved (Document resp) ETHLEL Elemer Lelik	Checked ETHGRY	Date 2015-05-15	Rev C	Reference

It is possible to reference environment variables in the following fields with the syntax “[ VariableName ]”:

- TTCN3preprocessorIncludes
- preprocessorIncludes
- SolarisSpecificLibraries
- Solaris8SpecificLibraries
- LinuxSpecificLibraries
- FreeBSDSpecificLibraries
- Win32SpecificLibraries
- linkerLibraries
- linkerLibrarySearchPath

The variables referenced with this syntax will be recognized by the Eclipse Designer plugin. If the tpd is used for makefile generation, the ttcn3\_makefilegen will replace the reference with its command line equivalent in the generated makefile. (e.g. [VariableName] => \$(VariableName) ).

Contents of the ProjectSpecificRulesGenerator element:

Exactly one GeneratorCommand element that specifies the external command to be run

An optional Targets element that contains any number of Target elements, each element having two attributes: name – name of the target, placement – the place of where the target shall be inserted. Possible places are defined in the TPD.xsd file.

#### 8.6.1.2 Local Build Settings

**Table 33 Elements of LocalBuildSettings**

Name of the element	Default value	O/M
MakefileFlags	empty	O
MakefileScript	empty	O
workingDirectory	N/A	O

MakefileScript is a script which modifies the Makefile generated by the makefilegen program or by the TITAN Designer internal makefile generator. This kind of script is widely used to automatically insert or remove flags which are not handled by the ttcn3\_makefilegen. If the Makefile is generated by the TITAN Designer, this script is generally not necessary because the TITAN Designer can handle (insert or remove) them but even in this case there can be necessary modifications. Duplicated insertion of flags can cause errors.

Please note, that the MakefileScript and workingDirectory paths are stored either relative to the root of the project, or with full path.

Prepared (Subject resp) ETHBAAT Jeno Balasko		No. 2/198 17-CRL 113 200/5 Uen		
Approved (Document resp) ETHLEL Elemer Lelik	Checked ETHGRY	Date 2015-05-15	Rev C	Reference

### 8.6.1.3 Remote Build Properties

RemoteBuildProperties contains a sequence of elements type of “RemoteHost” and one optional ParallelExecution element which is a boolean. A RemoteHost contains 3 elements according to Table 34 Elements of RemoteHost.

Table 34 Elements of RemoteHost

Name of the element	Type	O/M
Active	boolean	M
Name	string	M
Command	string	M

### 8.6.1.4 Naming Conventions

The naming conventions are given using Java regular expressions. All of the elements below are optional.

Table 35 Elements of NamingConventions

Name of the element	Default value	O/M
TTCN3ModuleName	.*	O
ASN1ModuleName	.*	O
altstep	as_.*	O
globalConstant	cg_.*	O
externalConstant	ec_.*	O
function	f_.*	O
externalFunction	ef_.*	O
moduleParameter	m.*	O
globalPort	.*_PT	O
globalTemplate	t.*	O
testcase	tc_.*	O
globalTimer	T.*	O

Prepared (Subject resp) ETHBAAT Jenő Balasko		No. 2/198 17-CRL 113 200/5 Uen		
Approved (Document resp) ETHLEL Elemer Lelik	Checked ETHGRY	Date 2015-05-15	Rev C	Reference

type	.*	O
group	[A-Z].*	O
localConstant	cl.*	O
localVariable	vl.*	O
localTemplate	t.*	O
localVariableTemplate	vt.*	O
localTimer	TL_.*	O
formalParameter	pl_.*	O
componentConstant	c_.*	O
componentVariable	v_.*	O
componentTimer	T_.*	O

Other than the above mentioned on the project level there is one more called: `enableProjectSpecificSettings` with being empty as the default value. This element makes it possible to override the global settings.

On folder level the extra node is called `enableFolderSpecificSettings` with being empty as the default value. This element makes it possible to override the global settings.

### 8.6.1.5 Configuration Requirements

The `ConfigurationRequirements` element stores a list of `ConfigurationRequirement` elements, each of which describes a single configuration requirement for a referenced project. For each referenced project there can be maximally one `ConfigurationRequirement` element. If there is no requirement against the actual configuration of a referenced project this element is missing.

**Table 36 Elements of ConfigurationRequirement**

Name of the element	Meaning	O/M
projectName	Stores the name of the project for which the requirement applies.	M
requiredConfiguration	Stores the name of the required project configuration as known by the referenced project.	M

Prepared (Subject resp) ETHBAAT Jenő Balasko		No. 2/198 17-CRL 113 200/5 Uen		
Approved (Document resp) ETHLEL Elemer Lelik	Checked ETHGRY	Date 2015-05-15	Rev C	Reference

## 8.6.2 Folder Properties

The `FolderProperties` element contains a list of `FolderResource` elements each of which contains all information related to the actual settings of the folders in a given build configuration. The `FolderResource` element contains a `FolderPath` and a `FolderProperties` subelement.

**Table 37 Elements of `FolderResource`**

Name of the element	Meaning	O/M
<code>FolderPath</code>	The path of the folder in the eclipse resource system.	O
<code>FolderProperties</code>	The actual properties of the folder.	O

**Table 38 The optional elements of the `FolderProperties` sub element**

Name of the element	Default value	O/M
<code>ExcludeFromBuild</code>	false	O
<code>centralStorage</code>	false	O
<code>NamingConventions</code>	Missing if all elements are on default value	O

For more information about the `NamingConventions` element please refer to 8.6.1.4

## 8.6.3 File Properties

The `FileProperties` element contains a list of `FileResource` elements each of which contains all information related to the actual settings of the files in a given build configuration. The `FilePath` and the `FileProperties` subelements are mandatory.

**Table 39 Elements of `FileResource`**

Name of the element	Meaning	O/M
<code>FilePath</code>	The path of the file in the eclipse resource system.	M
<code>FileProperties</code>	The actual properties of the file. see Table 40	M

**Table 40 Elements of the `FileProperties` sub element**

Name of the element	Default value	O/M
<code>ExcludeFromBuild</code>	false	O

## 8.7 Packed Referenced Projects

The `PackedReferencedProjects` element stores a list of `PackedReferencedProject` elements, each of them describes a single project reachable from the actual one or from referenced projects via project referencing.

The elements of this list are the same as `TITAN_Project_File_Information` but they cannot contain `PackedReferencesProjects`. All referred projects in the project chain are listed in this list.

A single `PackedProjectReference` element stores the same data in the same manner as it is stored in the referenced project but it cannot store the element `PackedReferencedProjects`.

Prepared (Subject resp)		No.		
ETHBAAT Jenő Balasko		2/198 17-CRL 113 200/5 Uen

## 8.8 Important Information, Limitations

We can only save settings related to the TITAN Designer plug-in. The settings of other plug-ins, related to the actual project, needs to be handled by the user separately.

**From our point of view data loss and corruption of any kind and magnitude is acceptable, as long as it does not involve TITAN Designer specific settings directly.**

Prepared (Subject resp) ETHBAAT Jeno Balasko		No. 2/198 17-CRL 113 200/5 Uen		
Approved (Document resp) ETHLEL Elemer Lelik	Checked ETHGRY	Date 2015-05-15	Rev C	Reference

The import is recreating the structure and the content of the project, not the project as a whole. For example: if on the source side there is a resource called X.ttcn located in the file system as Y.ttcn, after saving and loading this information at another location the created project will also have a resource called X.ttcn located in the file system as Y.ttcn. However as the 2 projects are located at different locations in the file system, the reference used to point to this file will be different.

In case the file was originally located in the source project, and is now linked in the loaded project, the resource will be decorated accordingly by the platform.

We support eclipse path variables, by saving the location info of the resource using them in a form where this information is available. However as this is an eclipse internal feature outside of our control, command line processing might be limited, or limiting the user. If a required path variable is not defined at the loading side, the resource will be created, but later on, when the platform tries to resolve it, the user might get some kind of error message.

It is also important to know, that we save the location information of all files and folders as Eclipse knows it. By default this means only local file system locations, however Eclipse can be extended with additional plug-ins to support remote operations (like FTP, HTTP, SSH connections) or virtual file systems.

If such features are used it is the user's responsibility to make sure, that the needed plug-ins are available on every machine where the project is to be used. Also when doing command line builds, their build scripts must be prepared to support such features.

In order to be able to recreate the whole project structure all referenced projects have to be saved as well. Otherwise we would not be able to load a missing referenced project.

However once loaded these projects can be used intermixed with other kinds of project inside Eclipse. For example it is possible to refer to them from not yet saved projects.

In case of a referenced project we only store the location where it was loaded from, or where it was saved to first. If it is saved to a new location it must be loaded first, otherwise the changes will be lost. However inside eclipse the project will still contain all the changes.

In the command line referenced projects are identified by the location of their descriptor, in eclipse they are identified by the name of the project. This means, that if a project to be referenced is loaded on a different name, the referencing project will not see it, and at load time will load it again. Also if a different project is loaded at an expected name, it will be used instead of the one being referenced.

ETHLEL Elemer Lelik	ETHGRY	2015-05-15	C	

In eclipse all information is persisted by the platform, as such the closing and re-opening of the workspace will not change any project information, or come with data loss.

This is our own project information; it can not be expected from external tool vendors to support it. As such exporting/importing a project via the ClearCase Remote Client will not be possible using this format, or might not produce the expected results.

## 9 XSD to TTCN-3 Converter

The XSD to TTCN-3 converter is converting XSD components to TTCN-3 modules according to the ETSI standard ES 201 873-9 (part 9 of the TTCN-3 standard).

The **XSD to TTCN-3 converter** takes as input one or more schemas written in XML Schema and produces one or more TTCN-3 modules containing a set of type definitions and encoding instructions to keep the same XML encoding, in such a way that there is one-to-one correspondence between TTCN-3 values and valid XML instances.

### 9.1 Terminology

For the purposes of the present section the following definitions apply:

### 9.2 Schema Component

Schema component is the generic XSD term for the building blocks that comprise the abstract data model of the schema.

#### 9.2.1 Schema Document

A schema document contains a collection of schema components, assembled in a *schema* element information item. The target namespace of the schema document may be defined (specified by the *targetNamespace* attribute of the *schema* element) or may be absent (identified by a missing *targetNamespace* attribute of the *schema* element). The latter case is handled in this document as a particular case of the target namespace being defined.

#### 9.2.2 Target TTCN-3 Module

This is the TTCN-3 module, generated during the conversion, to which the TTCN-3 definition produced by the translation of a given XSD declaration or definition is added.

#### 9.2.3 XML Schema

An XML Schema is represented by a set of schema documents forming a complete specification (i.e. all definitions and references are completely defined). The set may be composed of one or more schema documents, and in the latter case identifying one or more target namespaces. More than one schema documents of the set may have the same target namespace.

Prepared (Subject resp) ETHBAAT Jeno Balasko		No. 2/198 17-CRL 113 200/5 Uen		
Approved (Document resp) ETHLEL Elemer Lelik	Checked ETHGRY	Date 2015-05-15	Rev C	Reference

### 9.3 Command-line Syntax

The command line syntax of the converter is the following:

```
xsd2ttcn [-cepstVwx] [-f file] schema.xsd [-  
schema.xsd...]
```

or

```
xsd2ttcn -v
```

The XSD to TTCN-3 converter takes the name of files containing XML schemas as arguments (usually with the extension .xsd). The converter expects input files to be plain text files.

The following command line options are available (listed in alphabetical order):

-c

Disables the generation of comments derived from top level XML comments and also from XSD annotations and notations. TTCN-3 comments derived from XSD annotations and notations contain the actual character data of the nested XSD 'documentation' or 'appinfo' elements.

-e

Disables the generation of encoding instructions for TTCN-3 types and modules.

-f file

The list of the XSD files will be taken from the given file instead of the command line. The file format is a white-space separated list of XSD files. (Other XSD files in the command line will not be taken into account if this option is used.)

-p

Disables the generation of `UsefulTtcn3Types` and XSD predefined modules.

-s

Instructs the converter to parse the given XML schemas and perform only syntactic analysis on them (well-formedness check), but not to generate TTCN-3 output. This option is useful if you do not wish to generate TTCN-3 files when debugging an XML Schema.

-t

Prepared (Subject resp) ETHBAAT Jenö Balasko		No. 2/198 17-CRL 113 200/5 Uen		
Approved (Document resp) ETHLEL Elemer Lelik	Checked ETHGRY	Date 2015-05-15	Rev C	Reference

Disables the generation of timing information in TTCN-3 modules. These parts are the changing parts of the generated modules. By using this switch it is possible to generate TTCN-3 modules that will be the same even if time and version change.

-v

Prints version and license key information and exits.

-V

Disables status messages, for example, indicates which input file is currently being read, while converting.

-w

Suppresses warnings.

-x

Disables schema validation but generates TTCN-3 modules.

## 9.4 The Compilation Process for XML Schema

The XSD to TTCN-3 converter requires that each schema file used by the specification must be present in the input. From the input schema files, the converter will build one or possibly more independent TTCN-3 modules. The names of the output files (and the names of the TTCN-3 modules within) are set according to the value of the `targetNamespace` attribute defined in the schema element. Suffixes of TTCN-3 modules are `.tcn`.

Whenever a schema file contains an `import` element with the `namespace` attribute, all components (elements, types, groups, etc.) from that namespace are imported into the final XML schema. Note that there can be several schema files having one namespace. All components from that namespace are imported.

The following examples demonstrate how the XSD to TTCN-3 converter assembles input schema files to create the XML Schema.

### 9.4.1 Include

#### Example 1-1. 'include' with resolvable schemaLocation attribute

A.xsd:

```
<xsd:schema xmlns:xsd="http://www.w3.org/2001/XMLSchema"
  xmlns="http://www.example.org/xsd"
  targetNamespace="http://www.example.org/xsd">
  <xsd:include schemaLocation="B.xsd"/>
</xsd:schema>
```

B.xsd:

Prepared (Subject resp) ETHBAAT Jenö Balasko		No. 2/198 17-CRL 113 200/5 Uen		
Approved (Document resp) ETHLEL Elemer Lelik	Checked ETHGRY	Date 2015-05-15	Rev C	Reference

```
<xsd:schema xmlns:xsd="http://www.w3.org/2001/XMLSchema"
  xmlns="http://www.example.org/xsd"
  targetNamespace="http://www.example.org/xsd">
  ...
</xsd:schema>
```

converter command:

```
xsd2ttcn A.xsd B.xsd
```

In Example 1-1, the `schemaLocation` attribute indicates a schema file name that is present in the command line. The referenced schema file must be provided and listed in the command line.

## 9.4.2 Import

### Example 1-2. 'import' with resolvable schemaLocation attribute

A.xsd:

```
<xsd:schema xmlns:xsd="http://www.w3.org/2001/XMLSchema"
  xmlns="http://www.example.org/xsd"
  targetNamespace="http://www.example.org/xsd">
  <xsd:import namespace="http://www.example.org/xsd/B"
    schemaLocation="B.xsd"/>
  ...
</xsd:schema>
```

B.xsd:

```
<xsd:schema xmlns:xsd="http://www.w3.org/2001/XMLSchema"
  xmlns="http://www.example.org/xsd/B"
  targetNamespace="http://www.example.org/xsd/B">
  ...
</xsd:schema>
```

converter command:

```
xsd2ttcn A.xsd B.xsd
```

Example 1-3 shows the use of `import`. Schema A.xsd is importing schema B.xsd. The `schemaLocation` attribute in schema A.xsd is pointing to a schema file which is present on the command line input.

### Example 1-3. 'import' without schemaLocation attribute

A.xsd:

```
<xsd:schema xmlns:xsd="http://www.w3.org/2001/XMLSchema"
  xmlns="http://www.example.org/xsd"
  targetNamespace="http://www.example.org/xsd">
  <xsd:import namespace="http://www.example.org/xsd/B"/>
  ...
</xsd:schema>
```

B.xsd:

Prepared (Subject resp) ETHBAAT Jeno Balasko		No. 2/198 17-CRL 113 200/5 Uen		
Approved (Document resp) ETHLEL Elemer Lelik	Checked ETHGRY	Date 2015-05-15	Rev C	Reference

```
<xsd:schema xmlns:xsd="http://www.w3.org/2001/XMLSchema"
  xmlns="http://www.example.org/xsd/B"
  targetNamespace="http://www.example.org/xsd/B">
  ...
</xsd:schema>
```

**B2.xsd:**

```
<xsd:schema xmlns:xsd="http://www.w3.org/2001/XMLSchema"
  xmlns="http://www.example.org/xsd/B"
  targetNamespace="http://www.example.org/xsd/B">
  <xsd:include schemaLocation="http://www.example.org/xsd/B.xsd"/>
  ...
</xsd:schema>
```

**converter command:**

```
xsd2ttcn A.xsd B.xsd B2.xsd
```

An `import` with only `namespace` attribute, imports all the schemas present on the command line having the same `targetNamespace` as the value specified by the `namespace` attribute in the `import` element. In Example 1-3, `A.xsd` contains an `import` element having specified the `namespace` attribute only; the XSD to TTCN-3 converter will import both `B.xsd` and `B2.xsd`, as they have the same `targetNamespace` as the one defined in the `namespace` attribute of the `import` element from the schema `A.xsd`.

**Example 1-4. 'import' without namespace attribute****A.xsd:**

```
<xsd:schema xmlns:xsd="http://www.w3.org/2001/XMLSchema"
  xmlns="http://www.example.org/xsd"
  targetNamespace="http://www.example.org/xsd">
  <xsd:import schemaLocation="B.xsd"/>
  ...
</xsd:schema>
```

**B.xsd:**

```
<xsd:schema xmlns:xsd="http://www.w3.org/2001/XMLSchema">
  ...
</xsd:schema>
```

**converter command:**

```
xsd2ttcn A.xsd B.xsd
```

If the `import` element specifies the `schemaLocation` attribute only, the imported schema (`B.xsd`) should not be associated with any namespace; otherwise the converter reports an error message.

**Example 1-5. 'import' with no attributes****A.xsd:**

Prepared (Subject resp) ETHBAAT Jeno Balasko		No. 2/198 17-CRL 113 200/5 Uen		
Approved (Document resp) ETHLEL Elemer Lelik	Checked ETHGRY	Date 2015-05-15	Rev C	Reference

```
<xsd:schema xmlns:xsd="http://www.w3.org/2001/XMLSchema"
  xmlns="http://www.example.org/xsd"
  targetNamespace="http://www.example.org/xsd">
  <xsd:import/>
  ...
</xsd:schema>
```

converter command:

```
xsd2ttcn A.xsd B.xsd C.xsd D.xsd E.xsd F.xsd G.xsd H.xsd
```

The `import` statement with no attributes specified imports all the schema files in the command line input that have no `targetNamespace` specified. In Example 1-5, if `B.xsd`, `C.xsd`, and `H.xsd` are not associated with any namespace they are imported in the `A.xsd`.

## 9.5 Restrictions

Some features of XSD have no equivalent in TTCN-3 or make no sense when translated to the TTCN-3 language. Whenever possible, these features are translated into encoding instructions completing the TTCN-3 code. For any further information about unsupported features see [\[4\]](#).

Translation of the following XML schema elements is not supported:

`field`, `key`, `keyref`, `selector`, `unique` (identity-constraint definition schema components)

Translation of the following XML schema attributes is not supported:

`abstract`, `block`, `final`, `substitutionGroup`

XML schema attributes when they are used as attributes of schema element are ignored:

`blockDefault`, `finalDefault`, `id`, `version`, `xml:lang`

Specifying the number of fractional digits (by `fractionDigits` facet) for float types is not supported.

Numeric types are not allowed to be restricted by patterns.

List types are not allowed to be restricted by enumerations or patterns.

All time types restrict year to 4 digits.

Prepared (Subject resp) ETHBAAT Jeno Balasko		No. 2/198 17-CRL 113 200/5 Uen		
Approved (Document resp) ETHLEL Elemer Lelik	Checked ETHGRY	Date 2015-05-15	Rev C	Reference

## 10 Code Coverage of TTCN-3 Modules

The TTCN-3 compiler is able to instrument the generated C/C++ code for a set of TTCN-3 modules (= or files) to generate code coverage information during runtime. To enable this feature the `-K file` option needs to be used. For convenience this option is available for `ttn3_makefilegen` as well. It's possible to generate code coverage information only for a given set of TTCN-3 modules listed on the command line. In that case the set of files in `file` needs to be a subset of the files listed on the command line. If `file` contains a file which is not listed on the command line an error will be issued.

### 10.1 Generating Code Coverage

Assuming a project with the following files: `a.ttcn`, `b.ttcn`, `c.ttcn` in parallel mode and some PTCs during runtime were created. The scenario is the following:

- 5 Install LCOV. It's an external tool necessary to generate HTML output. Available here: <http://ltp.sourceforge.net/coverage/lcov.php> or can be installed using the package manager of your OS. This step needs to be performed only once.
- 6 Create an ASCII text file listing all the TTCN-3 modules to generate code coverage data for, one file name in a line. In this case we want to generate code coverage data for `a.ttcn` and `b.ttcn` and we're not interested in `c.ttcn`. Our `tcov_file_list.txt` will look like:

```
7 a.ttcn
```

```
8 b.ttcn
```

- 9 Generate a Makefile using `tcov_file_list.txt`:

```
10 ttn3_makefilegen -K tcov_file_list.txt -g -e mytest  
*.ttcn
```

- 11 Run: `make`

- 12 Then: `ttn3_start ./mytest`

- 13 (During runtime some `.tcd` XML files will be generated. Namely a `tcov-<component_id>.tcd` file per PTC and one for MTC.)

- 14 Collect and merge all `.tcd` files using `tcov2lcov` with default parameters:

```
15 tcov2lcov
```

Prepared (Subject resp) ETHBAAT Jenö Balasko		No. 2/198 17-CRL 113 200/5 Uen		
Approved (Document resp) ETHLEL Elemer Lelik	Checked ETHGRY	Date 2015-05-15	Rev C	Reference

16 (An `output.info` file will be generated in the current working directory. For more detailed information about `tcov2lcv` see 10.3.)

17 Generate HTML using LCOV's `genhtml` and the generated `output.info` (see 10.2 for more information):

```
18 genhtml --no-branch-coverage --t "Titan Coverage" --  
    legend output.info -o titan_coverage
```

19 Open `titan_coverage/index.html` in a browser.

## 10.2 Converting Code Coverage Data from XML to HTML

The `tcov2lcv` tool (binary tool) shipped with Titan and LCOV's `genhtml` tool (Perl script) are provided to generate human readable HTML from the Titan generated `.tcd` XML code coverage data files. LCOV's `genhtml` is not part of the Titan distribution and needs to be installed separately. The basic process is the following:

- 1 Execute `tcov2lcv` to collect and merge all the `.tcd` files generated during test execution. One `.tcd` file per component. By default an `output.info` file will be generated in the current working directory, which can be processed directly by LCOV's `genhtml`. More detailed information about `tcov2lcv` can be found in 10.3.
- 2 Execute `genhtml` with `output.info` as its input parameter. The recommended parameters are the following: `genhtml --no-branch-coverage -t "Titan Coverage" --legend output.info -o titan_coverage`. For more detailed introduction to `genhtml` and LCOV in general please read their user manuals at <http://ltp.sourceforge.net/coverage/lcov.php>.

## 10.3 Command Line Syntax of `tcov2lcv`

```
tcov2lcv [-h] [-b dir] [-d dir] [-o file] [-x xsd]
```

or

```
tcov2lcv -v
```

The Titan code coverage data to LCOV coverage data converter collects all valid `.tcd` XML files from a given directory recursively and generates a single ASCII text file suitable to be further processed by LCOV's `genhtml` tool to produce human readable HTML output. Please note that the output format generated by `tcov2lcv` is also human readable ASCII, but its only purpose is to provide an input for LCOV's `genhtml` tool. This format is LCOV specific and not documented here.

Prepared (Subject resp) ETHBAAT Jeno Balasko		No. 2/198 17-CRL 113 200/5 Uen		
Approved (Document resp) ETHLEL Elemer Lelik	Checked ETHGRY	Date 2015-05-15	Rev C	Reference

The following command line options are available (listed in alphabetical order):

`-b dir` (optional)

Set code base directory for source files. `dir` is usually the absolute path to the directory of the source files. This path is used as a common prefix for `genhtml`. The default value is the absolute path of the current working directory.

`-d dir` (optional)

`.tcd` files will be collected from `dir` recursively. By default the current working directory will be examined.

`-h` (optional)

Display help.

`-o file` (optional)

Set the name of the output file. The default file name is `output.info`.

`-x xsd` (optional)

Path to an XSD to validate all `.tcd` XML files found against. By default `$TTCN3_DIR/include/tcov.xsd` is used. This XSD file is part of the Titan distribution. If any of the `.tcd` files doesn't conform to the XSD an error will be given.

## 10.4 Limitations

The Titan compiler implements some optimizations which can affect the accuracy of the generated code coverage information. These optimizations cannot be turned off. The compile time evaluation of constant expressions can lead to untracked lines and statements (white in LCOV's HTML output) invisible to the code coverage information generator. These lines and statements are not counted as never-executed lines and statements (orange in LCOV's HTML output), so the statistics are not affected, but the end result can be confusing.

External functions are not yet supported and they're not shown in the statistics.

Prepared (Subject resp) ETHBAAT Jeno Balasko		No. 2/198 17-CRL 113 200/5 Uen		
Approved (Document resp) ETHLEL Elemer Lelik	Checked ETHGRY	Date 2015-05-15	Rev C	Reference

The Titan code coverage implementation is based on Titan's internal location tracking mechanism enabled by the `-L` compiler flag, which must be used together with `-K`. Sometimes it can lead to a little bit confusing or strange code coverage output. E.g. multiple location objects are generated when multiple variable declarations appear on the same line in the TTCN-3 source code. In this case the code coverage output will show that the given line is executed twice. For more complex statements like `for` three location objects are generated etc.

Prepared (Subject resp) ETHBAAT Jeno Balasko		No. 2/198 17-CRL 113 200/5 Uen

## 11 Tips & Troubleshooting

This chapter deals with various topics, which could not have been assigned to any of the previous chapters.

### 11.1 Type Aliasing

Type aliasing in TTCN–3 means that you can assign an alternative name to an existing type. The syntax is similar to a subtype definition, but the subtype restriction tag (value list or length restriction) is missing.

```
type MyType MyAlternativeName;
```

The type aliasing is implemented in the test executor, but it translates this TTCN–3 definition to a C `typedef` statement.

```
typedef MyType MyAlternativeName;
```

The limitation of the C `typedef` is that the C++ compiler cannot distinguish between the original and alias name in polymorphism (i.e. the identically named functions with parameter type `MyType` and `MyAlternativeName` are treated as same). That is, if you define a port type that allows the sending or receiving both of the original and aliased type, the generated C++ code cannot be compiled because the Test Port class contains two identical send/receive function.

As a work-around to this problem you can repeat the definition of the original type using the alternative name instead of type aliasing. In this case two differently named, but identical classes will be generated and the polymorphism problem will not occur.

### 11.2 Reusing Logged Values or Templates in TTCN–3 Code

Writing templates can be time-consuming task. To save some time and work, you can use the logs of the messages already sent or received to write templates.

If you would like to use a logged value in TTCN–3 code, then using the `logformat` utility (see the section 13.3 of the TITAN User Guide [\[13\]](#) about this utility) you have to follow these steps:

- 1 Start a text editor and open the (formatted) log file and the TTCN–3 source file.
- 2 Select and copy the desired value from the log file.
- 3 Paste the value at the corresponding position in the TTCN–3 code.

Prepared (Subject resp) ETHBAAT Jenö Balasko		No. 2/198 17-CRL 113 200/5 Uen		
Approved (Document resp) ETHLEL Elemer Lelik	Checked ETHGRY	Date 2015-05-15	Rev C	Reference

4 Finally, make the following changes:

- The enumerated values are followed by their numerical equivalents within parentheses. Delete them including the parentheses.
- If an octetstring value contains only visible ASCII characters, then the hexadecimal octetstring notation is followed by its character string representation between quotation marks and parentheses. Delete the character string (including the parentheses).
- If a `record`, `set`, `record of` or `set of` value contains no fields or elements, then the `logformat` utility changes the value from `{ }` to `{ (empty) }` in the log. Delete the word `(empty)` (including parentheses).

### 11.3 Using the TTCN-3 Preprocessing Functionality

Tips for the `Makefile` generated using the option `-p`:

- All the options for the C precompiler can be specified using the variable `CPPFLAGS_TTCN3`. Do not confuse it with the variable `CPPFLAGS`, which is used on the generated C++ code. If standard TTCN-3 output is needed the flag `-P` has to be added manually to the variable `CPPFLAGS_TTCN3`. The resulting `ttcn` files can be compiled with any TTCN-3 compiler (if other special language extensions are not used). Globally used preprocessor symbols can be defined here with the option `-D`. For example to compile the debug version of a project a `DEBUG` symbol can be specified with `-DDEBUG`.
- Files which are included in the `.ttcnpp` source files (with `#include`) and do not need to be translated can be specified in the `TTCN3_INCLUDES` variable. These files will be checked for modification when the `.ttcnpp` files are processed by `make`; any modification will trigger preprocessing of all the `.ttcnpp` files and the recompilation of the affected modules. If the suffix of a file is `.ttcnin` the Makefile Generator will add it to `TTCN3_INCLUDES`; in all other cases the file has to be added manually.
- Do not use any file name identical to the name of the intermediate file produced by the C preprocessor. The intermediate file name is generated by replacing the suffix `.ttcnpp` with `.ttcn`. Use the naming convention of naming the file as the module name avoiding such name collisions.
- The default C preprocessor used to preprocess TTCN-3 files can be replaced by editing the CPP variable.

There are minor issues when precompiling TTCN-3 code with a C preprocessor, these are resulting from the differences between the C and TTCN-3 languages. Tips for writing the `.ttcnpp` files:

Prepared (Subject resp) ETHBAAT Jenő Balasko		No. 2/198 17-CRL 113 200/5 Uen		
Approved (Document resp) ETHLEL Elemer Lelik	Checked ETHGRY	Date 2015-05-15	Rev C	Reference

- Do not define the B, O and H macros, these letters are used as part of the bitstring, octetstring and hexstring tokens in TTCN-3, but the C preprocessor will replace them.
- There are some predefined macros in the C preprocessor which will be always replaced, do not use any TTCN-3 identifier identical to these. These macros start with double underscore followed by uppercase letters. Some of the most common macros which might be useful:
  - `__FILE__`  
This macro expands to the name of the current input file, in the form of a C string constant.
  - `__LINE__`  
This macro expands to the current input line number, in the form of a decimal integer constant.
  - `__DATE__`  
This macro expands to a string constant that describes the date on which the preprocessor is being run.
  - `__TIME__`  
This macro expands to a string constant that describes the time at which the preprocessor is being run.

When writing preprocessor directives keep in mind that within the directive the C preprocessor syntax is in use, not the TTCN-3. Operators such as `defined` or `||` can be used.

Watch out for macro pitfalls, some well known are: side effects, misnesting, and operator precedence problems.

## 11.4 More Efficient Implementation of the Types `record of` and `set of`

The new implementation of the mentioned TTCN types and their ASN counterparts was introduced in TITAN version 1.7.pl2 (R7C). The performance of assigning `record of`/`set of` typed variables improved significantly since TITAN version 1.7.pl1 (R7B). The new implementation uses reference counting when an assignment is made. The whole data structure is copied only when necessary, for example, the user wants to modify its value. Using temporary variables improves the quality of the code.

## 11.5 Workflow for Native XML Support

In this very short and simple example we are presenting and explaining the procedure of using the XML encoding / decoding. Through the steps of the workflow you can understand the XML related possibilities of TITAN.

First look at data types. These are the base of every test. If you have data representation in XML format (XSD is the standard for defining data types), you have to convert it into the equivalent TTCN-3 data types using the XSD converter. This is a shortened variant of the commonly used SOAP protocol.

            </xs:sequence>
          </xs:complexType>
        </xs:element>
        <xs:element name="extension" type="AnySequenceType"
          minOccurs="0" />
      </xs:sequence>
    </xs:complexType>
  </xs:element>

  <xs:complexType name="AbstractSetAttributeType" abstract="true"/>

  <xs:element name="SetMODefinition"
type="AbstractSetAttributeType" abstract="true"/>

  <xs:complexType name="AnyMOIdType">
    <xs:sequence>
      <xs:any namespace="##any"
processContents="lax" maxOccurs="unbounded"/>
    </xs:sequence>
  </xs:complexType>

  <xs:complexType name="AnySequenceType">
    <xs:sequence>
      <xs:any namespace="##any"
processContents="lax" maxOccurs="unbounded"/>
    </xs:sequence>
  </xs:complexType>

  <xs:simpleType name="MoType">
    <xs:restriction base="xs:string">
      <xs:pattern value="[A-Za-z][_A-Za-z0-9]*@.*"/>
    </xs:restriction>
  </xs:simpleType>

</xs:schema>

```

After conversion you have a TTCN-3 module whose name is derived from the targetNamespace attribute of <schema> element. This module contains only data types. Two other files are generated also with standardized base datatypes:

- UsefulTtcn3Types.ttcn
- XSD.ttcn

The content of the generated TTCN-3 file:

Prepared (Subject resp) ETHBAAT Jeno Balasko		No. 2/198 17-CRL 113 200/5 Uen		
Approved (Document resp) ETHLEL Elemer Lelik	Checked ETHGRY	Date 2015-05-15	Rev C	Reference

```
module schemas_ericsson_com_cai3g1_2 {  
  
  import from XSD all;  
  
  type record Set  
  {  
    MoType mOType,  
    AnyMOIdType mOId,  
    record {  
      SetMODEfinition setMODEfinition  
    } mOAttributes,  
    AnySequenceType extension_ optional  
  }  
  
  with {  
    variant (mOType) "name as capitalized";  
    variant (mOId) "name as capitalized";  
    variant (mOAttributes) "name as capitalized";  
    variant (mOAttributes.setMODEfinition) "name as capitalized";  
    variant (extension_) "name as 'extension'";  
  };  
  
  type record AbstractSetAttributeType  
  {};  
  
  type AbstractSetAttributeType SetMODEfinition;  
  
  type record AnyMOIdType  
  {  
    record length(1 .. infinity) of XSD.String elem_list  
  }  
  
  with {  
    variant (elem_list) "untagged";  
    variant (elem_list[-]) "anyElement";  
  };  
  
  type record AnySequenceType  
  {  
    record length(1 .. infinity) of XSD.String elem_list  
  }  
  
  with {  
    variant (elem_list) "untagged";  
    variant (elem_list[-]) "anyElement";  
  };  
  
  type XSD.String MoType /* (pattern "[A-Za-z][_A-Za-z0-9]*@.*") */;  
  
  }  
  
  with {  
    encode "XML";  
    variant "namespace as 'http://schemas.ericsson.com/cai3g1.2/'";  
    variant "controlNamespace 'http://www.w3.org/2001/XMLSchema-instance' prefix  
    'xsi'";  
    variant "elementFormQualified";  
  }  
}
```

Also manually created type definitions can be used and combined together. This example shows the next module containing also data types.

Prepared (Subject resp) ETHBAAT Jeno Balasko		No. 2/198 17-CRL 113 200/5 Uen		
Approved (Document resp) ETHLEL Elemer Lelik	Checked ETHGRY	Date 2015-05-15	Rev C	Reference

```

module SOAP {

import from XSD all;
import from schemas_ericsson_com_cai3g1_2 all;

type record ApplicationHeaderContent
{};

type record ApplicationBodyContent {
    Set setRequest
};

type record SoapEnvelope {
    SoapHeader header optional,
    SoapBody body
}
with {
variant "name as 'Envelope'";
variant (header) "name as capitalized";
variant (body) "name as capitalized";
};

type record of ApplicationHeaderContent SoapHeader;

type union SoapBody {
    XSD.String fault,
    record of ApplicationBodyContent content
}
with {
variant (fault) "name as capitalized";
variant (content) "untagged";
variant (content[-]) "untagged";
};

}
with {
encode "XML";
variant "controlNamespace 'http://www.w3.org/2001/XMLSchema-instance' prefix
'xsi'";
variant "namespace as 'http://schemas.xmlsoap.org/soap/envelope/' prefix 'SOAP-
ENV'";
variant "namespace as 'http://schemas.xmlsoap.org/soap/encoding/' prefix 'SOAP-
ENC'";
variant "namespace as 'http://schemas.ericsson.com/cai3g1.1/' prefix 'ns3'";
}

```

The XML encoding/decoding can be accessed via external functions. To encode a value of the SoapEnvelope type (the top-level record type in our example) to XML, or to decode XML data into a value of SoapType, we can use external functions like the following:

Prepared (Subject resp) ETHBAAT Jeno Balasko		No. 2/198 17-CRL 113 200/5 Uen		
Approved (Document resp) ETHLEL Elemer Lelik	Checked ETHGRY	Date 2015-05-15	Rev C	Reference

```
module SOAP_ExternalFunctions {  
  
    import from SOAP all;  
  
    external function enc_SOAP(in SoapEnvelope pdu) return octetstring  
    with { extension "prototype (convert) encode(XER:XER_EXTENDED)" }  
  
    external function dec_SOAP(in octetstring stream) return SoapEnvelope  
    with { extension "prototype (convert) decode(XER:XER_EXTENDED)" }  
  
}
```

The “prototype (convert)” attribute instructs the compiler to generate a C++ implementation for each of the external functions (see section 4.22.4 above). This permits the use of the encoding/decoding functions directly from TTCN-3 code.

In case more sophisticated processing is required (or some form of pre/post-processing), the encoder/decoder functions can be reimplemented in C++. The basic functionality provided by the compiler can be used as a starting point. Note that in this case all the “with” attributes in the example above must be removed from the external function declaration (otherwise the compiler will generate the functions again with the same signature and duplicate symbol errors will appear at link time).

For representing the usage of encoding and decoding we created this demo module that contains one template definition and in the testcase we will apply encoding and decoding.

Prepared (Subject resp) ETHBAAT Jeno Balasko		No. 2/198 17-CRL 113 200/5 Uen		
Approved (Document resp) ETHLEL Elemer Lelik	Checked ETHGRY	Date 2015-05-15	Rev C	Reference

```

module demo {

import from SOAP all;
import from SOAP_ExternalFunctions all;

template SoapEnvelope SoapTemplate :=
{
  header := omit,
  body := {
    content := { {
      setRequest := {
        mOType      := "JB007",
        mOId        := {
          elem_list := {
            "<catalog><books count='3'/></catalog>",
            "<catalog><movies count='1'/></catalog>"
          }
        },
        mOAttributes := {
          setMODefinition := {
          }
        },
      },
      extension_ := omit
    }
  }
}

type component SOAP_CT
{
  var octetstring v_encodedPDU, v_decodePDU;
  var SoapEnvelope v_decodedPDU;
}

testcase tc_encdec() runs on SOAP_CT
{
  v_encodedPDU := enc_SOAP(valueof(SoapTemplate));

  v_decodedPDU := dec_SOAP(v_encodedPDU);

  log("Encoded set request (SoapEnvelope): ", v_encodedPDU);
  log("Decoded set request (SoapEnvelope): ", v_decodedPDU);
}

control
{
  execute(tc_encdec());
}
}

```

The complete demo project is now ready. If running the test case a log file will be generated in which we can find the encoded representation of the value and the decoded variant.

The resulting XML encoding:

      </ns3:setRequest>
    </ns3:ApplicationBodyContent>
  </ns3:Body>
</ns3:Envelope>
The decoded format (a TTCN-3 value of type SoapEnvelope)

```

```

{
  header := omit,
  body := {
    content := { {
      setRequest := {
        mOType      := "JB007",
        mOId        := {
          elem_list := {
            "<catalog><books count='3'/></catalog>",
            "<catalog><movies count='1'/></catalog>"
          }
        },
        mOAttributes := {
          setMODefinition := {
          }
        },
        extension_ := omit
      }
    } }
  }
}

```

## 11.6 Debug Memory Use of Record/set of Types

One of the common source of the memory leakage in the TTCN test suite is the ever-growing record/set of's. In order to help the debug of such issue, the test suite should be compiled with -DTITAN\_MEMORY\_DEBUG\_SET\_RECORD\_OF flag added to CPPFLAGS in the Makefile.

That flag activates a WARNING log statement, issued after every 1000<sup>th</sup> element added to the record/set of.

Example:

Prepared (Subject resp) ETHBAAT Jeno Balasko		No. 2/198 17-CRL 113 200/5 Uen		
Approved (Document resp) ETHLEL Elemer Lelik	Checked ETHGRY	Date 2015-05-15	Rev C	Reference

```

module test {

    type component test_CT {}
    type record of charstring roc

    testcase tc_test() runs on test_CT
    {
        var roc r:={}
        var integer k

        for(k:=0;k<10001;k:=k+1){
            r[sizeof(r)]:="a";
        }
    }

    control
    {
        execute(tc_test())
    }

}

```

Running of the example test above will produce the following log:

```

MTC@esekilxxen1844: Warning: New size of type @test.roc: 1000
MTC@esekilxxen1844: Warning: New size of type @test.roc: 2000
MTC@esekilxxen1844: Warning: New size of type @test.roc: 3000
MTC@esekilxxen1844: Warning: New size of type @test.roc: 4000
MTC@esekilxxen1844: Warning: New size of type @test.roc: 5000
MTC@esekilxxen1844: Warning: New size of type @test.roc: 6000
MTC@esekilxxen1844: Warning: New size of type @test.roc: 7000
MTC@esekilxxen1844: Warning: New size of type @test.roc: 8000
MTC@esekilxxen1844: Warning: New size of type @test.roc: 9000
MTC@esekilxxen1844: Warning: New size of type @test.roc: 10000

```

Table 26	Statistics filters, grouped lists.....	265
Table 27	The sequence of elements of TITAN_Project_File_Information ..	271
Table 28	Attributes of ReferencedProject .....	272
Table 29	The attributes of FileResource and FolderResource .....	273
Table 30	Attributes of PathVariable.....	274
Table 31	Elements of Configuration .....	275
Table 32	The elements of MakefileSettings .....	276
Table 33	Elements of LocalBuildSettings .....	279
Table 34	Elements of RemoteHost .....	280
Table 35	Elements of NamingConventions.....	280
Table 36	Elements of ConfigurationRequirement .....	281
Table 37	Elements of FolderResource.....	282
Table 38	The optional elements of the FolderProperties sub element	282
Table 39	Elements of FileResource .....	282
Table 40	Elements of the FileProperties sub element.....	283

## 15 Abbreviations

API	Application Programming Interface
ASCII	American Standard Code for Information Interchange
ASN.1	Abstract Syntax Notation One
ATS	Abstract Test Suite
BER	Basic Encoding Rules (of ASN.1)
BNF	Backus–Naur Formalism
CER	Canonical Encoding Rules (of ASN.1)
CPP	Cello Packet Platform
CR	Change Request
DER	Distinguished Encoding Rules (of ASN.1)
DNS	Domain Name Server
DTD	Document Type Description
ETS	Executable Test Suite
ETSI	European Telecommunications Standards Institute
FIFO	First In, First Out
GCC	GNU Compiler Collection

Prepared (Subject resp) ETHBAAT Jeno Balasko		No. 2/198 17-CRL 113 200/5 Uen		
Approved (Document resp) ETHLEL Elemer Lelik	Checked ETHGRY	Date 2015-05-15	Rev C	Reference

GUI	Graphical User Interface
HC	Host Controller
HTML	Hypertext Markup Language
HTTP	HyperText Transfer Protocol
IDL	Interface Description Language
IE	Information Element
IP	Internet Protocol
ISO	International Organization for Standardization
LCOV	A graphical front-end for GCC's coverage testing tool
LSB	Least Significant Bit
MC	Main Controller
MSB	Most Significant Bit
MTC	Main (or Master) Test Component
OSE	Open System Environment
PDU	Protocol Data Unit
pl	Patch Level
PTC	Parallel Test Component
PT	Port Type
SOAP	Simple Object Access Protocol
SUT	System Under Test
TC	Test Component (either MTC or PTC)
TCC	Test Competence Center
TCP	Transmission Control Protocol
TLV	Tag, length, value
TPD	Titan Project Descriptor
TR	Trouble Report
TTCN	Testing and Test Control Notation
TTCN-2	Tree and Tabular Combined Notation version 2
TTCN-3	Tree and Tabular Combined Notation version 3 (formerly)
	Testing and Test Control Notation (new resolution)
UDP	User Datagram Protocol
URL	Universal Resource Locator
URI	Uniform Resource Identifier
W3C	World Wide Web Consortium
XML	W3C Extensible Markup Language
XSD	W3C XML Schema Definition
